numerous workshops and elaborates their contents and the organization of pottery production, a boon to archaeologists. In *Maya Potters' Indigenous Knowledge: Cognition, Engagement, and Practice* (2018) Arnold drew upon engagement theory to describe the indigenous knowledge of traditional Maya potters in Ticul. In this heavily illustrated narrative account, he examines craftspersons' knowledge and skills, their engagement with their natural and social environments, the raw materials they use, and the process for making pottery. Following Lambros Malafouris, Tim Ingold, and Colin Renfrew, Arnold argues that potters' indigenous knowledge is not just in their minds but extends to their engagement with the environment, raw materials, and the pottery-making process itself and is recursively affected by visual and tactile feedback. More recently Yumi Park Huntington, Arnold, and Johanna Minich have edited textbook and reader, *Ceramics of Ancient America: Multidisciplinary Approaches* (2018) that combine methodologies from art history, archaeology, and ethnography. The introductory essay by the editors is enlightening and further demonstrates Arnold's interdisciplinary skills.

In the late 1960s, Arnold demonstrated that one of the principal components (palygorskite), an azure pigment used by the ancient Maya called Maya Blue, was still being used by contemporary Maya (1967a, b; Arnold and Bohor 1975). He demonstrated that the modern Yucatec Maya were aware of its unique properties and used it for pottery temper and for the treatment of illnesses (Arnold 1967a, 1967b, 1971, 2005c, 2008, 2012; Arnold et al. 2007a). Arnold is currently writing a book about Maya Blue, and he is also preparing a report of the excavations of the Inca site of Cata-casa-llaqta on the edge of Cuzco, Peru, that he co-excavated with colleagues from the National Institute of Culture in 1972–1973.

Dean E. Arnold continues to attend professional meetings to advise and mentor his colleagues and help us better understand pottery and the people who made, used, and discarded them – a tenant of ceramic ecology. He is the earliest founder of ceramic ethnoarchaeology, doing it and publishing before Carol Kramer and William A. Longacre. Arnold is a gentleman and gentle man, beloved by his peers and students and rightly called by many the "Dean of Ceramic Studies."

Arqueologia Industrial

José Manuel Lopes Cordeiro
Minho University, Braga, Portugal

Basic Information

Arqueologia Industrial is a biannual peer-reviewed academic journal published by the Portuguese Society for Industrial Heritage (Associação Portuguesa para o Património Industrial), which is the Portuguese National Representative of The International Committee for the Conservation of the Industrial Heritage (TICCIH), with the support of the River Ave Valley Textile Industry Museum, edited by José Manuel Lopes Cordeiro (Minho University, Braga, Portugal). *Arqueologia Industrial* publishes scholarly research, essays, and reviews of books published in the field of industrial archaeology and its museology.

Recent issues published articles on archaeological works in a lime kiln at Madeira Island, the social and urban space of Vista Alegre Porcelain Factory, or the archaeology of a Brazilian iron mill (seventeenth-eighteenth centuries). The debate on the creation of an international heritage charter on industrial heritage by ICOMOS with the cooperation of TICCIH was also discussed in current issues. Future directions will seek to address issues of industrial landscapes, reuse of industrial heritage, and the use of industrial heritage for tourism purposes.

Official website: http://www.museudaindustriatextil.org.

Major Impact

The first issue of *Arqueologia Industrial* was published in 1987, as a newsletter of the Industrial Archaeology Program of the University of Minho Archaeology Unit. Two numbers were published in 1987 and 1988. The aim was to create a periodical that would meet the interest on industrial archaeology which then began to assert themselves in Portugal. The success of this initiative led to transform the newsletter into a scientific journal, allowing a deeper approach of their subject. After finding a sponsor, the journal restarted its publication in 1993 with its second series, under the project of the River Ave Valley Textile Industry Museum, being published jointly by the Industrial Archaeology Program and the Vila Nova de Famalicão County Council, on a biannual publication frequency, but corresponding to a double issue. Unfortunately, due to several difficulties, the journal was forced to stop its publication, returning with its third series in 1997, under the project of the Oporto Museum of Science and Industry, and published two numbers, also on a biannual frequency. Due to the extinction of the Museum project, it was necessary to find another editor, to allow its continuity. The solution was found in 2005, and the fourth series has been published jointly by the Portuguese Society for Industrial Heritage (TICCIH Portugal) and the River Ave Valley Textile Industry Museum, again with the sponsorship of the Vila Nova de Famalicão County Council. It has been published regularly ever since, maintaining the biannual frequency (a double issue), extending its contents also to research on Brazil's industrial archaeology.

Arsebük, Güven

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Güven Arsebük was born in Istanbul in 1936. He graduated from Robert's College and, inspired by his high school literature teacher, decided to study archaeology. At this time there were two different certificate programs: in prehistory and classical archaeology in the Archaeology Department of Istanbul University. Arsebük graduated from the prehistory program in 1962.

In 1963 and 1964, during his military service, he translated L.S.B. Leakey's *Adam's Ancestors: The Evolution of Man and His Culture* into Turkish. Following his military duty, he went to the University of Tubingen to study anthropology, genetics, Paleolithic, prehistory, and ethnology education for a year under the Thyssen scholarship. On return to Turkey he was assigned to Istanbul University as professorial assistant in 1966.

With a Fulbright scholarship he took lectures at the University of Chicago including human evolution from F. Clark Howell, science of Paleolithic ages from L. Freeman, Pleistocene geography from K. Butzer, and prehistory from Robert J. Braidwood. He received his M.A. in 1964.

Arsebük was promoted to associate professor in 1981, becoming a professor in 1990 following the publication of his book *Human and Evolution*.

Major Accomplishments

Arsebük is considered one of the pioneering archaeologists who developed anthropological and archaeological methods on the "human"-based approach. He, for the first time in Turkish archaeological tradition, examined an archaeological subject using an anthropological method in his Ph.D. dissertation titled "The Relations Problematic

Between Karas Type and Dark Burnished Ware Pottery in Altınova."

After his undergraduate study he participated in many excavations and projects such as the 1958 Side excavations led by Arif Müfid Mansel, following on from 1959 to 1961 Hattuşa directed by Kurt Bittel. Arsebük also participated in the salvage and conservation project for ancient monuments of Lower Euphrates and Keban. As well, with Ufuk Esin, he worked on the Tepecik, Tülintepe, and Değirmentepe excavations.

Güven Arsebük led an international team in excavations between 1988 and 1990, revealing the oldest Paleolithic settlement in Turkey to date. The Yarımburgaz Cave, located in the Küçükçekmece district in İstanbul, was dated from 400,000 to 150,000 BP.

Güven Arsebük served as a representative of Istanbul University's Faculty of Literature for UNESCO from 1990 to 1993. He is a board member of the American Research Institute in Turkey, a member of the American Association of Physical Anthropology in New York, a founder and member of the Turkish Institute of Archaeology, a member of the Germen Institute of Archaeology, and a member of New York Academy of Sciences and of the Turkish Academy of Sciences.

Art Origins: The Emergence of Graphic Symbolism

Marcos García-Diez[1] and Blanca Ochoa[2]

[1]Department of Prehistory, Ancient History and Archaeology, Complutense University of Madrid (UCM), Madrid, Spain

[2]Department of Geography, Prehistory and Archaeology, University of the Basque Country (UPV/EHU), Vitoria, Spain

State of Knowledge and Current Debates

Introduction

We have all asked ourselves when art first appeared; when humans first drew, painted, engraved, or sculpted forms in order to transmit concepts and ideas different from their formal materiality. It is not easy to answer that question because the information is based on archaeological evidence (with the limitations that this implies in terms of the object and the contextualization of

its chronology and use) and modern conditioning factors about the understanding of the objects.

The first consideration is obvious: what is art? To discuss this would be to enter an unending debate. To avoid that, as it is not the objective of this book, it is preferable to express our position directly. Art is a tangible creation through which the author, either an individual or a representative of a society, potentially transmits an idea or concept which goes (or may go) beyond formal materialization; a "formal vehicle" that a person or a group endows with a particular meaning. Therefore, it is a formal constructed graphic language, perceived and understood by the members of the human group that created it and which may also possess a potential meaning beyond the "precise moment" of its creation and thus possess a sense of timelessness.

It should also be added that art is not necessarily associated with beauty. The current state of discussion of this topic in our discipline has demonstrated that aspect of beauty forms part of the "vehicle" of the meaning that the forms generate in the observer and interpreter of the graphic creation. This is to say that with a greater perception of beauty (something that pleases the eye and, by extension, the "spirit" of the observer), there is great ease of comprehension and/or acceptance of the message.

The study of the origins of art, or graphic languages, is not simple as we do not possess all the evidence that would enable a precise conclusion. However, archaeology, with the material evidence that has reached us and which it has succeeded in discovering, is endeavoring to seek the origins. It is a constant and intense search in which scientific debate is not out of place.

Human Singularity and Symbolism: Commonplaces, Origins, and Developments

When we talk or write about artistic creations, it is not unusual for people to regard them as a human singularity. It is something that distinguishes us from other animals. Therefore, art and its origin and development are closely linked to biological, cognitive, behavioral, and also philosophical concepts.

The bipartite view that defined human exclusiveness, both cultural and physical, has now been overcome. According to anatomical morphology, about six million years ago, we separated from an ancestor (*Sahelanthropus tchadensis*) that linked us with chimpanzees, from which we barely differ genetically. From that time, anthropologists identify traits that define the hominization process: changes in dentition, modification of skeletal structure leading to an erect posture and bipedalism, and gradual increase in brain size. Those and other changes slowly followed one another in a process that took different directions, resulting in alterations to the diet, metabolism, and, ultimately, in our ontogenesis.

The increase in brain size and weight very probably represent the greatest singularity of human primates in biological terms. In the first 1.5 million years the brain size of our genus doubled its volume and in the 2.5 million years of its existence it has grown at least threefold. This growth also implied modification in brain morphology.

These changes permitted the consolidation of previously acquired skills and the development of others –new capacities of planning and awareness linked to cognitive skills, which in their most complex form involve, among other abilities, rationalization, abstraction, reflexion, intellection, creation, structuration, and ranking – that involved modifying elements in the natural environment and the construction of exosomatic materialities. Those skills and abilities correspond to processes and changes that are the responses to interactions. These involve possible solutions that when they consolidate as repeated strategies result in adaptations of the species or group. Interactions between individuals of the same species, interactions with other species, and interactions with changing environmental factors define relationships and physical and cultural modifications that generate mechanisms and strategies for adaptation and survival, or otherwise extinction.

The systematization and later socialization of skills, and the adaptation to diverse natural and social environments, determine survival as a species and singularize the Homo genus.

What other forms of evidence make the human primate unique and when and where did they occur? Or indeed, what archaeological information is available? A brief and simple answer might propose that it was the construction of symbols, of new socially accepted extrasomatic realities. In this setting, the creation of graphic languages, including art, is one of the most important forms of evidence and helps to define us. It is a skill and ability that is closely linked to the sense of death and other phenomena that cannot always be traced easily by archaeology.

However, imbuing certain materials or certain actions with a meaning that goes beyond their materiality can be identified in the archaeological record despite the difficulties. One of these is the fact that archaeology is limited by the tangible nature of the remains, which implies the difficulty in documenting actions that leave no physical trace.

Media symbolism, or media, has been interpreted as representative of "modern behavior" (Zilhão 2011), as it integrates individual or collective actions linked to burials, the acquisition of an oral system of articulated communication, the production and transformation of materials with a social dimension (like ochre and personal adornments), and the construction of graphic symbolism, such as art. These forms of behavior and their emergence and development correspond to adaptations closely connected with biological and socio-demographic causes that result in changes in the relationships between individuals (Mithen 1996; Shennan 2001). Before discussing art, the other forms of evidence of symbolism will be briefly reviewed.

Burials and Death

Death is a biological fact, involving the termination of a physical materiality, that is, the end of life of a living organism, and a transformation that provokes diverse feelings and responses, depending on the species; thus, different forms of behavior have been described for humans and non-human primates (Cronin et al. 2011).

However, does the fact of death in the Homo genus display any singularity? The archaeological record has documented human remains several million years old, some of which were found in domestic contexts, which may imply that the body was a source of food. However, in some cases cannibalism can be linked to ritual purposes, with a symbolic component. This has been proposed for the remains from Homo antecessor to the Bronze Age (Saladié and Rodriguez-Hidalgo 2017).

The oldest accumulation of human bodies in a separate place away from a domestic setting corresponds to *Homo heidelbergensis* (Sima de los Huesos, Atapuerca, Spain), with an age of 400,000 years (Carbonell et al. 2003). This case has been taken as an early example of the link between a place and the dead, in the sense of our concept of a cemetery.

The archaeological record corresponding to *Homo neanderthalensis* and *Homo sapiens*, from about 120,000 years ago, displays a gradually more abundant repetition of evidence in Europe, Asia, and Africa (Pettitt 2011). The protection of the bodies becomes more frequent, as well as the presence of potentially symbolic elements buried with the dead; ochre, animal remains, stone tools, beads, and even the presence of flowers have been suggested. Following bereavement, humans conceive abstract feelings that seek transcendence and endow the deceased with a social dimension. These are symbolic feelings that go beyond the behavior of animal primates and possibly arise out of the absence of answers to reflections on immateriality, non-life, and afterlife.

Adornments

The conception and use of adornments made from sea shells, teeth, and pieces of bone and ivory are documented in a concrete pattern of emergence and expansion (d'Errico and Stringer 2011; Zilhão 2013): the first evidence in Africa about 120,000 years ago, the subsequent spread to Europe and Asia, and a widespread use about 40,000 years ago. It is a form of behavior that has been identified among both *Homo neanderthalensis* and *Homo sapiens*.

It is not easy to determine their function, but they obviously served some social and/or personal function. Based on ethnographic analogies, the creation and use of personal adornments are

linked to ideas of beauty and of identification of a family or clan, or they may indicate a social position or intra-social differentiation, although not necessarily in the same way as our concept of vertical ranking. Their symbolic value is evident, and also their objective of seeking to transmit an idea, a concept, or an image with supra-individual implications.

Body Paint and Decoration

The interpretation of the value of symbolism mediated through body paint is still undecided (Wadley et al. 2009; d'Errico et al. 2009) and only the application of ethnographic models in combination with archaeological findings will enable progress to be made. Working with coloring matter has been proposed at African sites of about 275,000 years of age (as Twin Rivers and Sai Island sites), but it was with *Homo sapiens* and *Homo neanderthalensis* that evidence of pigment being crushed into powder or affected by heat becomes more common (Soressi and d'Errico 2007).

The presence of these pigments, mainly red hues, has been regarded as representative of symbolic behavior (body paint for social and/or group differentiation), although some scholars prefer functional interpretations (to protect the skin, for medicinal purposes, conservation, hafting implements, etc.). It is not easy to decide on any explanation. However, anthropology shows that the hypothesis of body decoration cannot be discarded and striations caused by use-wear on the surfaces of coloring matter and the preparation of pigments by mixing minerals support its feasibility, but cannot be discarded the hypothesis the striations caused by use-wear on the surfaces of coloring matter.

Verbal Language: Invisible Symbolism

Human evolution involved the development and consolidation of social skills: the formation of singular strategies connected with the ability to carry out group activities implying degrees of organization, understanding, and cohesion. Among other factors, a verbal language (with a particular structure, varied vocabulary, conceptualization based on abstraction, and varied recursiveness, as well as a possible symbolic dimension) must have been essential for positive and full communication.

Anthropological studies of the vocal tract, auditory system, the ability of speech, and the neuronal development of some brain areas (Krause et al. 2007; Christianses and Kirby 2003; Martínez et al. 2008; Quam et al. 2016) show that language was not exclusive to our species, *Homo sapiens*. However, capacity is potential; the possession of those similarities does not necessarily imply that those humans enjoyed a language resembling ours. It is likely that the context, and subsistence and social pressure, would determine its development and complexity.

The Traditional View of the Emergence of Art: Historiography and the Academic Background Until 20 Years Ago

The scientific community in general assumed that the origin of art was exclusively linked to the European Anatomically Modern Human. The great theoreticians of the twentieth century, the French prehistorians Breuil (1952) and Leroi-Gourhan (1965), constructed their ideas on prehistoric art based on that axiom. Consequently, until recently it was widely accepted that: (a) the earliest possible date for the emergence of art would be about 40,000 or 35,000 years ago (BP, before the present); (b) its appearance was connected exclusively with the European Upper Palaeolithic; and (c) its development should be understood in terms of an evolutionary conception of forms. The biological, cultural, and philosophical setting of this assumption was the singularity not only of humans but of our species. Thus, it was the "first biological me" (the first European *Homo sapiens*) who developed art, artistic creations, and formal graphic languages.

However, what was the reason for this assumption? Did any data exist with which to propose a time limit and the link between art and a single human species? In fact, very little information, often of dubious quality, existed. Engraved figurative portable art was (and still is) scarce or does not exist in some regions until 20,000 years BP. For rock art, no objective numerical dates had been obtained; no precise dates to attribute a

creation to one time or another. Only superimpositions of motifs had been documented, where it was only known which motif had been produced first or last in a relative order.

However, the most powerful conditioning factor was the construction and consideration of the term *Homo sapiens*. When Linnaeus (1758) proposed it in the mid-eighteenth century, it was not based on metric or morphological traits as we might define *Homo sapiens* today. For the naturalist, *Homo sapiens* corresponded to a wise person, capable of understanding, with abstract reasoning and the capacity of introspection and speculation, who used linguistic systems and performed conceptual and symbolic operations. In other words, the definition did not come from the traits of physical anthropology but from cognitive factors.

Over time, with the discovery and description of new species (e.g., *Homo neanderthalensis* in 1864, *Homo erectus* in 1892 and *Homo heidelbergensis* in 1908), the term *Homo sapiens* became increasingly based on the anatomic conceptualization (to differentiate our species with the newly described ones) and it lost its original sense and meaning.

During this semantic change, an equation was drafted and it has been maintained as an axiom until till recently. *Homo sapiens* is equal to the (only) human capable of creating symbols and therefore of creating artistic works that contain and transmit an idea.

But what exactly did those researchers propose regarding the origins of art? Breuil and Leroi-Gourhan constructed chrono-stylistic schemes to express their ideas. In the early twentieth century, Breuil (1952) affirmed that in its origins (about 40,000 BP, at the start of the Aurignacian-Gravettian cycle) the first art consisted of finger-fluting in clay (curved lines forming meanders, sometimes parallel or with the appearance of macaroni), red hand paintings, large red discs or dots, red or engraved lines (including some radial types that he defined as huts), and red X-shapes. He also noted the existence of some animal figures that were very simple in their outlines, anatomical details and perspective, and generally incomplete. His criteria to classify the depictions were superimposition in (seemingly) diachronic panels and an evolutionary perspective that he applied to the different motifs, the simpler, the older they were.

In the mid-twentieth century, Leroi-Gourhan (1965) proposed a new scheme for European prehistoric art based on styles. The oldest, Style I, which began in about 32,000 BP, included what he interpreted as genital symbols, mainly attributed to the female gender, and animals drawn with very simple lines and designs. He also considered the existence of cupmarks carved into the rock and lines on bones. However, in the same period of time in which he defined Style I, in 1964 he published his book *Le Geste et la Parole* (Leroi-Gourhan 1964–1965), which imagined a phase before that first style. He called this a prefigurative style and determined that it would have started about 50,000 BP and consequently must have been linked to *Homo neanderthalensis*, as *Homo sapiens* could not have reached Western Europe earlier than 45,000 BP. In this phase he included lines (sometimes crossing over each other and sometimes parallel) engraved on bones and less often on stones, which had been found mostly in France and only on portable objects. It should be noted that although Leroi-Gourhan continued to work almost until his death, he did not develop or comment on that first style any further.

It was Lorblanchet, in his book *La naissance de l'art. Genèse de l'art préhistorique* (1999), who essayed a study of the bones and stones with "marks" that could be attributed to "Homo erectus, Neanderthals and proto-Cro-Magnon." His study concluded by highlighting the existence of intentional and symbolic linear motifs on bones and stones, some of them simple and others more complex and organized. He also acknowledged exceptional cases of geometric forms that might also be attributed a symbolic intention.

Therefore, it can be affirmed that until a few years ago it was generally thought that rock art (or parietal art, the art on walls) began with signs and some simple animal figures in about 40,000 or 35,000 BP, that is to say in connection with anatomically modern humans.

In contrast, for portable art (decoration on bones, stones, antlers, etc.) there was no

consensus. While some researchers accepted the existence of linear and geometric engravings associated with human species paleontologically prior to *Homo sapiens*, others rejected that possibility either out of simple incredulity or because they thought that the lines were not created intentionally but by various taphonomic processes (such as grooves caused by trampling, butchering animals, etc.).

The Origin and Initial Development of Art or Graphic Symbolism in Europe

The study of the first formal graphic language is based on the oldest evidence of altering natural elements as a form of media. Graphic constructions are a kind of formal language (art?) constructed with lines and groups of lines that form linear, geometric, and exceptionally natural (zoomorph and anthropomorph) structures. As explained above, although this form of behavior has traditionally been associated with anatomically modern humans in Europe, an increasing number of older examples are being documented in Europe.

Evidence of Portable art before Anatomically Modern Humans

Graphic behavior has been documented in early stages of the Palaeolithic in Europe. The oldest evidence was associated with a Lower Palaeolithic group of stone flakes in Bulgaria. It is a bone with series of lines, found at the site of Kozarnica and dated to a million years ago (Guadelli and Guadelli 2004). It should be noted that there is no consensus in the scientific community as to whether this can be regarded as portable art, as some researchers suggest that these lines might be butchery marks.

In contrast, greater agreement has been reached about a group of engravings at the German site of Bilzingsleben, dated to between 350,000 and 250,000 years ago (Mania and Mania 1988; Mania 1991; Steguweit 1999). Some bones display more or less parallel lines while one contained a series of parallel lines in a vertical position "framed" by oblique lines (Fig. 1a). Another motif clearly tends to a geometric pattern: a double rectangle whose interior is associated with lines (Fig. 1b). However, the most surprising object is a bone with lines that create a figurative motif (Fig. 1c): an indeterminable animal of which the body, head, and a forelimb can be clearly distinguished. The representation is very simple, but with the necessary reservations, its figurative character seems evident. In this case, it would be one of the oldest figures known.

Art Origins: The Emergence of Graphic Symbolism, Fig. 1 Bone artifacts from Bilzingsleben dated between 350,000 and 250,000 BP. (**a**) Organized and rhythmic linear composition; (**b**) motif tending toward a geometric shape; (**c**) figurative representation of an indeterminate animal (Dietrich Mania)

Art Origins: The Emergence of Graphic Symbolism, Fig. 2 (**a**) Stone artifact from Axlor dated in about 45,000 BP with a cross-shaped linear motif (Marcos García-Diez et al.). (**b**) cupmarks on a boulder at the site of La Ferrasie associated with Neanderthal burials (Michel Lorblanchet)

However, the numbers of examples, as well as the thematic diversity of the linear compositions, increase in the Mousterian (Lorblanchet 1999; García-Diez et al. 2013a; Zilhão 2013). From about 150,000 BP onward, the number of objects with simple linear motifs gradually increases and has been documented at such sites as Abri Suard, Saint Anne I, Oldisleben 1, Vaufrey, Tata, El Castillo, and Prolom II. From about 60,000 BP, in the middle and final phases of the Middle Palaeolithic, the number of objects and motifs increases further, on both bones and stones (e.g., at Le Moustier, Abri Lartet, Marillac, Le Petit Puymoyen, La Quina, Cotencher, La Ferrassie, L'Ermitage, Turské Mastale, Axlor – Fig. 2a – and Temnata). These portable objects display diverse linear patterns, sometimes based on lines arranged in a rhythmic, ordered, and hierarchic composition. They are mainly constructions formed by straight, more or less parallel lines. They coexist with other representations in Europe, such as the cupmarks at La Ferrassie (Fig. 2b) associated with human burials or the highly debated "Neanderthal mask" at La Roche-Cotard.

Evidence of Rock Art Before Anatomically Modern Humans

Just as graphic symbolism has been documented on portable objects more than 40,000 years old, the evidence of rock art associated with Neanderthal populations has recently gained strength via a series of new direct dates.

Dating rock art is not simple. Until a few years ago the only method in use was radiocarbon dating by accelerator mass spectrometer, and this could only be applied to motifs drawn with charcoal, organic matter, or organic binders. This meant that most motifs painted in red, mainly with iron oxides, and engravings could not be dated.

However, recent advances in the Uranium-Thorium method now allow very small samples of calcite to be dated and precise results to be obtained. Since some parietal motifs are partially covered by calcite, or were painted on top of calcite, it is therefore possible to obtain dates that give an idea of the time when the paintings were produced. This method can provide either an ante quem date (when the figure is beneath the calcite and must have been painted before that date) or a post quem date (when the figure is on top of calcite and must have been painted after that date).

After studying the stratigraphic relationship between the paintings and the calcite (i.e., which is on top and which is underneath), samples were recently taken in several caves in Spain and France with rock art that was thought to belong to an early period. Over 500 results were obtained. In three Spanish caves, the results have shown that the paintings were more than 40,000 years old and therefore from a time before anatomically modern humans reached the Iberian Peninsula (Hoffmann et al. 2018).

La Pasiega Cave in Cantabria, Spain, is a well-known important Palaeolithic rock art site, on UNESCO's World Heritage list. Studies carried out in the cave have identified hundreds of painted and engraved animal figures and symbols. In its maze-like passages, one of them, called Galería C, contains a panel with red signs and animals. A ladder-shaped sign (Fig. 3) consisting of two parallel vertical lines with horizontal lines at different heights is partly covered by a small calcite formation that was dated by the U-Th method. The three results obtained show that this sign was painted over 64,800 years ago (Hoffmann et al. 2018).

Similar results were achieved in the center of the Iberian Peninsula, in Maltravieso Cave in Cáceres. A stencilled hand (Fig. 4) produced by placing the hand on the wall and spraying red pigment around it using a rudimentary air-brush was dated to at least 66,700 BP (Hoffmann et al. 2018).

And in the south of Spain, in Ardales Cave in the Province of Malaga, as many as 12 significant dates were obtained. The samples were all taken on a large pillar where geological processes had formed calcite "curtains" with "pleats" that curve in and out (Fig. 5a). Red pigment had been sprayed on both the concave and convex parts of these to create elliptical shapes. It was possible to take samples from both above and below the pigment and associated with different shapes (Fig. 5b). The results showed that these red paintings were first produced before 65,500 years ago, that a second phase of graphic activity took place between 48,700 and 45,300 years ago, and very probably a third one between 45,500 and 38,600 BP (Hoffmann et al. 2018).

All these results confirm the existence of rock art inside caves at a time when the Iberian Peninsula was inhabited by Neanderthals. Those human populations used a non-figurative type of graphic language (shapes formed by dots and lines, and hands that from a creative perspective cannot be considered figurative as they correspond to the shape around a hand placed against a wall) produced with red pigment. Their position inside the caves, the need for a form of lighting, the preparation of the pigment and its mixing with water, and the application technique (by spraying, at least in Maltravieso and Ardales) confirm the intentional character and therefore human origin of the graphic activity.

Additionally, the confirmation in Ardales Cave of several phases of activity in precisely the same passage and on the same surfaces indicates the repetition of shapes and languages and the use of parietal motifs that were included in later

Art Origins: The Emergence of Graphic Symbolism, Fig. 3 Red ladder-shaped motif in La Pasiega Cave painted at least 64,800 years ago (Dirk Hoffmann et al.)

creations. This shows that forms of communication existed, implying the transmission of information connected with the decorated places. However, we also have to consider that transmission of ideas probably experienced changes from one to the next episode changing the meaning, function, and significance but not the vehicle. This gave those places a monumental character and a symbolic significance that transcended the motifs themselves.

These results and the conclusions derived from them shatter the traditional conception of rock art exclusively attributable to anatomically modern humans. Above all, they allow cave art to be explored and understood in a different way. How can it be denied now that some stencilled hands, discs, and simple linear signs were the graphic creations of *Homo neanderthalensis*? Could the discs and hands in such caves as El Castillo in Spain or Merveilles in France have been painted by Neanderthal humans? This does not mean that all the hands (García-Diez et al. 2015) and discs were Neanderthal creations. It must now be accepted that some artistic forms were generated in a particular time (whenever that was) and lasted over time until they were reused from the graphic point of view with the same or a different symbolic meaning (d'Errico et al. 2016). This is very human behavior and should not surprise us.

Thus, we know that in Ardales Cave, Neanderthal humans made use of the iconography generated hundreds or thousands of years before by anatomically similar groups. And this symbolic space was equally used as a symbolic place by later human groups belonging to the species *Homo sapiens* (Cantalejo et al. 2006). Other cases of the repetition of motifs have been documented in El Castillo Cave (Pike et al. 2012; García-Diez et al. 2018) in a time before 35,000 BP and even the reuse of figures is evident in the same cave. In a visually clearer way, in Altamira Cave, figures were created on the

Art Origins: The Emergence of Graphic Symbolism, Fig. 4 Red hand stencil in Maltravieso Cave painted at least 66,700 years ago (Dirk Hoffmann et al.)

Ceiling of the Polychromes during at least 25,000 years (García-Diez et al. 2013b).

Another example of rock art associated with populations older than anatomically modern humans is the group of engraved lines in Gorham's Cave in Gibraltar (Rodríguez-Vidal et al. 2014).

The Origin and Initial Development of Art or Graphic Symbolism in Asia

The appreciation of the symbolic and graphic abilities of human societies in Europe must be assessed against a wider geographic background. Although Europe used to be regarded as the continent where graphic symbolism emerged and from where it dispersed to other regions, new discoveries are challenging that Eurocentric view and it has become necessary to consider the evidence in Africa and Asia.

In Asia, the oldest evidence was found at the site of Trinil; it is associated with *Homo erectus* and is dated in about 540,000 BP. It is freshwater mollusk shell on which more or less parallel and angular lines were engraved (Fig. 6) and which have been related to the cognitive sphere and capacities of neuromotor control (Joordens et al. 2015).

At a more recent time, in at least 105,000 BP, at Lingjing (Li et al. 2019) flat bones were engraved with approximately parallel lines (Fig. 7a) and ochre was used to highlight the engravings. It has been suggested that these engravings were the work of Denisovan humans. A stone at Qafzeh in Israel, dated in about 95,000 BP, was engraved with mostly parallel straight lines. Finally, a stone

Art Origins: The Emergence of Graphic Symbolism, Fig. 5 Ardales Cave. (**a**) column on which oval-shaped motifs were drawn between at least 65,500 years ago and 38,600 years ago. (**b**) detail of one of the color stains that has been dated (Dirk Hoffmann et al.)

at Quneitra (Marshack 1996) in Syria, with a date of 60,000 BP, contains numerous parallel lines, some of them forming a kind of repeated semicircular shape (Fig. 7b).

One of the most significant objects in Asia, although also problematic, was found at the site of Berekhat Ram (d'Errico and Nowell 2000) in the Golan Heights, on the borders of Israel, Lebanon, Jordan, and Syria. It must have been produced by *Homo erectus* as it has been dated to at least 230,000 BP. A series of incisions were made in a small reddish volcanic rock and some surfaces were abraded possibly to make them smoother. The stone is naturally in the shape of the human body, with the head differentiated from the torso, and the breasts from the torso. This artifact has therefore been considered as a feminine anthropomorphic figurine (Fig. 8a), and specific human actions have been identified in the differentiation of its anatomical regions. It is not exactly a sculpted figure, but a natural stone whose shape attracted the attention of someone who

Art Origins: The Emergence of Graphic Symbolism, Fig. 6 Shell from Trinil with angular and approximately parallel lines, dated in 540,000 BP (Josephine Joordens et al.)

Art Origins: The Emergence of Graphic Symbolism, Fig. 7 (**a**) Lingjing, plaque with roughly parallel lines dated in 105,000 BP (Francesco d'Errico and Luc Doyon). (**b**) stone artifact from Quneitra with roughly parallel lines, some of them with a reiterated semicircular form (Alexander Marshack and Christopher Henshilwood)

emphasized the anatomical features it suggested. If this is correct, and it seems quite feasible, it would be one of the first figurative representations documented in the archaeological record.

The Origin and Initial Development of Art or Graphic Symbolism in Africa

In a similar way to the previous figure from the Golan Heights, at an Acheulean site dated to at

Art Origins: The Emergence of Graphic Symbolism, Fig. 8 "Proto-sculptures." (**a**) From Berekhat Ram, dated in at least 230,000 BP, a volcanic rock with a natural human shape which was modified to stress its female form (Pinterest). (**b**) From Tan-Tan, dated in about 300,000 BP, a quartzite stone with a natural human shape which was modified with lines to differentiate anatomical regions and emphasize its suggestive shape (Der Spiegel)

least 300,000 BP a quartzite object was found in a natural shape that suggested a human figure with the head, torso, and lower limbs. This is the proto-sculpture from Tan-Tan in Morocco (Bednarik 2003) to which some small modifications were made and which may have been painted as remains of hematite have been identified on its surface (Fig. 8b). However, its acceptance in the scientific community is significantly less positive than in the case of the figure from Berekhat Ram.

Some other objects in Africa predate anatomically modern humans as they are reliably dated to about 200,000 BP, but there is no consensus. Possibly the clearest example was found in Wonderwerk Cave (South Africa) where a stone plaque displays approximately parallel lines and is dated no later than 270,000 BP (Bednarik and Beaumont 2012).

However, the most representative and unquestionable evidence of early graphic activity in the continent comes from the Middle Stone Age, in an archaeological and anthropological context of *Homo sapiens*. Some objects with linear engravings (Henshilwood and Marean 2011; d'Errico et al. 2012), dated to at least 100,000 BP, have been recorded at Pinnacle Point, Klasies River Mouth caves, Hollow rock shelter, and Border Cave, among other sites.

The South African site of Blombos Cave (Henshilwood et al. 2018) has provided an important ensemble of graphic evidence in a time between 97,000 and nearly 70,000 BP. Different techniques (incised engraving and drawing in red) were applied on surfaces of bone and ochre. Two objects display linear decoration consisting of parallel and angular lines forming a pseudo-zigzag, one of them partially framed in a possibly rectangular shape (Fig. 9).

A little more modern, between 65,000 and 59,000 BP, are the ostrich egg shells decorated with geometric motifs in Diepkloof (Texier et al. 2010) and Lipdrift (Henshilwood et al. 2014) shelter. In both cases the linear decoration exhibits a certain degree of compositional complexity, as series of parallel lines and cross-hatching can be observed in an organized and structured design (Fig. 10).

This range of archaeological evidence has accumulated mostly in the last 20 years, during which time d'Errico's research has played a major role in assessing the importance of those objects. They imply questioning the notion of the European origins of art.

However, for the Asian and African sites, it must be accepted that graphic symbolism was linked to the development of cognitive abilities

Art Origins: The Emergence of Graphic Symbolism, Fig. 9 Stone from Blombos Cave with a pseudo-zigzag motif framed inside a possible rectangular shape and dated in 77,000 BP (Stephen Alvarez)

and the construction of visual representations that were shared within the human group in order to transmit information. The iteration of linear motifs, particularly compositions based on parallel and sometimes angular lines, which occasionally became more complex with cross-hatched motifs, indicates a certain degree of graphic regularity.

In a diachronic sense, more or less organized linear compositions are documented on both continents associated with earlier human species. Thus, in Asia they are found from 500,000 BP onward but become relatively more frequent after 125,000 or 100,000 BP. This relationship between density of finds and chronology is repeated in Africa, where from about 100,000 BP onward examples of graphic activity become relatively more numerous, although in connection with anatomically modern humans. Additionally, great diversity is seen in the compositions, and some scholars have attempted to differentiate "regionalisms," such as in the case of the ostrich egg shells.

One final aspect, which may be quite important, was the use of stones with a natural shape that suggested the human body and which were modified slightly to indicate anatomical features or regions. Few examples have been found, but it seems that these "proto-sculptures" can be interpreted as the first graphic evidence based on the formal use of suggestive perceptions that involved anthropogenic modifications. These objects were probably created in Asia about 230,000 years ago, and possibly in Africa 300,000 years ago, in both cases associated with archaic human species.

Toward an Appraisal of the Origins of Art and the First Graphic Symbolism

Making use of the environment with cognitive abilities and skills is constant among primates, but the human singularity lies in the capacity to modify it and create new materialities.

Another ability of the Homo genus is the construction of materialities that express meaning beyond their tangible form. In this context, graphic forms were artificial social containers of information and new means of relationships among members of a group. The information they contained was governed by the social rules determined by the individual or social group. Nature was transformed, new materialities were created, and they were given a new meaning, thus creating an "artificial nature" with a human origin.

Examples that have been described representing the emergence of graphic behavior show that these cognitive abilities and skills are not necessarily limited to anatomically modern humans. In contrast, they demonstrate an association with *Homo erectus*, *Homo heidelbergensis*, and *Homo neanderthalensis*, and it has even been suggested with Denisovan humans.

It is still too early to attempt an overall account of the origins and development of this graphic

Art Origins: The Emergence of Graphic Symbolism, Fig. 10 Ostrich eggshell fragments with diverse linear motifs, dated in 60,000 BP (Pierre-Jean Texier et al.)

symbolism. There is disperse evidence of linear motifs in Europe from at least about 250,000 BP, in Asia from about 540,000 BP and in Africa from at least 270,000 BP. In the three continents the engraved motifs and compositions are based on parallel and angular lines, while in Europe some rectangular geometric shapes have been recorded.

Some simple figurative motifs have been documented on the three continents in a time of about 300,000 or 250,000 BP. The clearest examples at Bilzingsleben and Berekhat Ram, and the most problematic (because of the lack of exact evidence) at Tan-Tan, certify the existence of very simple animal depictions (which do not

allow the animal species to be identified) and the use of natural suggestive shapes that were altered slightly to emphasize the human appearance of the stone, in a kind of "proto-sculpture." These examples demonstrate the cognitive ability of archaic humans who were able to perceive the shape and alter it slightly with technical actions that imply abstraction of reality, mental transformation of it and an alteration of nature through shapes created using neuromotor control.

With the available data, it is possible to provisionally propose a second phase within the emergence of graphic symbolism. In Europe from about 150,000–100,000 BP onward, in Asia from 100,000 BP, and in Africa also from about 100,000 BP, the number of known examples in the archaeological record increases, although they are still scarce. The difference is that, while in Europe and Asia these examples were created by early humans (*Homo neanderthalensis*, *Homo erectus*, and Denisovan humans), in Africa they were the work of anatomically modern humans. More evidence has been documented in the latter continent and possible graphic regionalisms may have arisen, representing graphic and symbolic formulas that were intended to mark social and group identities.

In Europe, from at least 60,000 BP, with the presence of Neanderthal populations, portable objects display greater evidence of motifs that continue to be mostly linear. However, those groups also achieved a new symbolic landmark in the social transcendence and durability of graphic communication systems.

The certification of rock art in caves with an age of at least 65,000 years demonstrates the capacity not only of creating but also of transferring communication condensed in symbols and in confined places. This creativity also acquired a timeless quality as those graphic representations lasted in time after they had been produced and may have been seen by later human populations that even used them with the same or a different meaning. These symbols were depicted in underground spaces which acted like a "hard disk" in which the motifs and information were stored for later times.

Different intensities in the presence of graphic symbolism can be detected over at least 500,000 years during the development of the skills and abilities of graphic representation. A gradually more frequent presence of this evidence of social interaction and communicative behavior can be documented on a timeline, revealing a progressively greater social importance of those media, attesting to changes in cultural, social, and territorial organization of the human groups, possibly as a consequence of modifications in the demographic structure.

With the advent of anatomically modern humans in Europe, rock and portable art acquired a new dimension as it became socially more important in different parts of the planet. Regionalism grew increasingly accentuated as animal figures and a previously unknown diversity of linear and geometric structures (signs) appeared. It is still necessary to obtain numerical dates for the ensembles and understand the territorial extent of Palaeolithic art to advance in the comprehension of how humans created those graphic structures to transmit information and condition social and cultural development.

A Final Brief Reflection

In recent years great progress has been made in prehistory as regards the cognitive dimension. The study of graphic representations has shown that the characteristics Linnaeus attributed to his definition of *Homo sapiens* are not exclusive to Homo paleontologically sapiens populations or anatomically modern humans. *Homo erectus*, *Homo heidelbergensis*, *Homo neanderthalensis*, and even Denisovans conceptualized external reality and transmitted information using graphic languages based on shapes.

This means that from a cognitive point of view, following Linnaeus, we should reserve the term *Homo sapiens* exclusively to Homo paleontologically sapiens populations or we should make clear if this term is being used in an anatomical or cognitive sense or even conceived in a genetic way.

In any case, it is now clear that symbolic abilities and skills of a graphic nature, based on the construction of motifs, have existed for at least 500,000 years, associated with anatomically archaic humans. The presence of those media, with their implications for communication and

social interaction, is being identified over gradually longer timespans, as has been explained.

Future Perspectives

The study of the origin and development of graphic symbolism is currently an important subject of scientific debate. Our understanding of this archaeological reality has varied greatly in the last 20 years, and therefore the present state of our knowledge will surely also change.

To make progress, add nuances and modify the data and conclusions, we must work on dating the rock art and understanding the density of Neanderthal graphic production. When did it begin? What is its spatiotemporal distribution? It is possible that the chronological attribution of some representations, especially non-figurative motifs, currently assigned to the early Upper Palaeolithic, should be reconsidered. We must also overcome the Eurocentric standpoint that conditions our territorial understanding of the phenomenon and be open to any non-European evidence that has been well-tested chronologically.

At the same time, it is necessary to reexamine from a taphonomic perspective engraved bone or stone objects that have been attributed to anatomically archaic humans and discard any examples in which the lines are due to natural causes or are butchery marks. This will achieve a better understanding of the phenomenon and the density of evidence. It is also important to contextualize the objects chronologically in order to understand how graphic symbolism emerged in each region and its possible dispersion.

Art Studies: Normative Approaches

María Isabel Hernández Llosas
National Council on Scientific Research of Argentina – CONICET, University of Buenos Aires, Buenos Aires, Argentina

Introduction and Definition

The theoretical proposals that search for regularities, or "norms," in different materials of the archaeological record have been very important since the beginnings of archaeology and are still foundations for current scientific research. Nevertheless, their success, failure, or relative advantages have been marked by the different interpretations that each theoretical approach has applied to the regularities found in the archaeological record.

For the archaeology of art, throughout the history of the discipline, various normative approaches have been developed, some with applications for portable art and others for rock art. These have varied according to particular situations in different academic contexts.

In the USA the normative approaches have been more linked to the general concepts of the "Culture-History School," which in its North American trend adopted particular features which differentiated it from similar approaches in other parts of the world. In this case, it was intimately linked to "normative theory" (sensu Binford 1965), which has applied fundamentally to portable art research, particularly in the study of pottery designs, looking for recurrent features that would allow the definition of "ceramic styles."

On the other hand, in Europe, the search for regularities in terms of shared norms has been more related to postulates based on Structuralism, Semiotics and Cognition, and has been specifically applied to Paleolithic parietal art research.

Historical Background

Normativism Inspired in the "Culture-History School"

In spite of the fact that the "Culture-History School" has had great influence in the development of archaeology, both in Europe and America, in its specific relation to the archaeology of art, the North American branch of this school has been more prominent, particularly in respect to portable art and monumental art.

In North America the Culture-History School is best represented by the work of Whilley and Phillips (1958), in which "cultural areas" were defined for the American continent and "chronological-cultural periods" were proposed to tackle the pre-Hispanic occupation of the continent. The characterization of the areas and the periods was carried out from an inductive epistemology which held the notion that "culture" was a "mental norm" shared by the members of a society.

Such a notion starts from a passive vision of material culture, considering it as an expression of such mental norms. The temporal-spatial distribution of material culture with specific features was taken as an indicator of presence-absence of the "bearers of such norms," and these were understood as "archaeological cultures."

Art did not escape such conception, being interpreted as the materialization of ideas, and stylistic standardization as the graphic and concrete expression of cultural norms based on such ideas. Thus conceived, art in all its forms was taken as an indicator relevant to identify archaeological cultures, which helped in the characterization of periods and cultural areas.

The definition of "artistic styles" was carried out through the detailed description of designs and techniques of portable art and pottery (rock art was practically omitted from this and other theoretical frameworks of the American trend). After that, and following the identification of recurrent features, "styles" were defined, which were in turn associated, via induction, to a "culture" and to a "people."

Such "artistic styles" were considered as reflexes of cultural and symbolic norms of such people, whose members were seen as their "passive bearers." In sum, art was conceived as a passive means of expression of ideas, understood as "mental cultural norms."

These conceptions have had a great influence in the development of archaeology and a great part of the systematization of knowledge about American archaeology managed today has been established on its grounds.

In spite of these contributions, later theoretical proposals such as the New Archaeology have strongly criticized these conceptions and their results. In effect, Binford (1965, 2001) wrote a history of the development of "normativism" in North American archaeology, pointing out its important limitations and emphasizing that one of its more important flaws is to hinder the analysis of variability in the archaeological record.

In spite of the theoretical clash between the "normative theory" (sensu Binford) and Processualism-New Archaeology, there has been a great influence of the former over the latter. In effect, Lyman and O'Brien (2004) consider that as an alternative, many of the normative propositions are crystallized when they are explicitly used in the interpretations of the data generated by the New Archaeology followers. Thus, in relation to the archaeology of art, authors such as Deetz, Hill, Longacre, and Whallon (among other New Archaeology followers) developed studies of ceramic designs, and, when analyzing them statistically, they identified design groups which they interpreted as elements which were culturally and normatively significant (Lyman and O'Brien 2004).

Proposals Based on Structuralism, Semiotics, and Cognition

While in North American archaeology the "normative theory" was being developed, it was confronted with the "New Archaeology," and both were being applied in the archaeology of art, particularly in portable art analyses. Simultaneously, in Europe other theoretical lines were being applied, particularly to analyze rock art.

In effect, postulates based on Structuralism, Semiotics, and Cognition started to be used

towards the early 1960s, in order to face the study of European Paleolithic parietal art.

Such tenets, influenced by rationalist French thought, were applied mainly by Laming Emperaire (1962) and Leroi Gourhan (1965) to the study and interpretation of Paleolithic parietal art, considering that:

(a) It was the product of the projection of mental structures, crystallized in artistic creation.
(b) Such mental structures were organized through binary oppositions (proposed by Saussure's linguistics and Levi Strauss's structuralism).
(c) This was recognizable in rock art through the spatial distribution of specific motifs, which was not random but rather structured via determined oppositions and associations.

Taking these considerations into account, recurrences in motifs and their associations in specific places of the sites were searched for, interpreting them as symbolic expressions of myths, expressed via graphic forms, and which were spatially structured through dual associations (*mythograms*).

Specific combinations between motifs and with the bedrock topography entailed a specific meaning, whose analysis should be tackled considering them as the significant symbol associations and not as anecdotal tales of real or imaginary events. Such different combinations would have different meanings according to their topographic-iconographic structuration.

The analysis of these different topo-iconographical combinations should be carried out as if they were "grammatical structures," trying to access the underlying "syntax" or "grammatical code." Such analysis tended to access the knowledge of the "composition rules" which were implicit to the distribution of specific rock art motifs in specific bedrock locations, avoiding a literal interpretation or an exclusively symbolic interpretation, given that their deep meaning was actually lost.

Once the "composition rules" were identified, each of the two aforementioned authors carried out different structuralist analyses, focusing their attention on specific associations observed between animal figures and abstract designs of supposed sexual content. Each one constructed stylistic schemes using, also, elements of other theoretical approaches: such as diachronic cultural evolutionism and culture-history normativism, interpreting differently the nature of such recurrent combinations.

Such free interpretation within the same theoretical position, together with the identification of patterns which could not just be ascribed to a single "visual grammar," or to a specific "mythogram," is some of the main problems faced by this theoretical proposal.

Today, this proposal has been entirely discarded in terms of its interpretive aspects, but some of its contributions still persist and are mainly referred to methodological lines which provide relevant information, such as:

1. The search for chronological indicators in the combination of stratigraphic information with the assessment of superimpositions in art, the analysis of variations in techniques, and in stylistic conventions through time
2. The identification of the persistence of more than one "artistic style or stage" in relation to the duration of determined "lithic industry" found in an excavation
3. The interest for the study of the socioeconomic aspects of rock art production, as much as its social uses in the past, postulating that such aspects could only be accessible through the identification of recurrent patterns which are verifiable in the archaeological record

Problems, Contributions, and Perspectives from Normative Approaches

The proposals and applications of these normative theoretical frameworks need to be analyzed in the particular historical-academic contexts in which they were created and used. Only then can they be properly assessed in terms of their problems and contributions to current research.

Firstly, in the two mentioned cases, a great interest in *developing methodological tools* is observed: these are particularly oriented towards ways of tackling time and space in the analysis of

different types of material culture related to portable art and rock art production. To this end, "periods" and "cultural areas" were established within American normative approaches, and "stages" and/or "styles" were defined within the French structuralism with cognitive-semiotic roots. This is understandable in these moments of history of archaeological research, in which absolute dating methods were lacking to date materials in the archaeological record (C14 dating was only available from 1955 onwards); thus, the priority was to have chronological referent for art's relative chronology and for its spatial distribution.

With the development of radiocarbon dating technique, and with the ample possibility of its use in excavated archaeological materials, around 1960 the urgent need to establish chronologies via relative methods diminished, although its importance did not (and does not) disappear, both for excavated materials and also, mainly, for most of rock art research.

In turn, the attempts to develop interpretive tools for regularities observed in the archaeological record were also product of particular situations of the trajectories of each of these theoretical proposals. Thus, *American normativism* was inclined to develop typological analyses, in order to observe similarities and differences in artifact types and complexes, with the end of identifying "archaeological cultures" and to determine limits among them. Established in this manner, each formal variation detected in the artifacts was interpreted as a chronological indicator. Such proposal was considered from the 1970s as a theory about "cultural transmission" in time and space. For this reason it was criticized, claiming that it ignored the great variability of the archaeological record, which was the product of intra- and intergroup differences in "cultural systems." Such criticism emphasized that the main wrong belief of normativism was to assume that archaeological societies were internally homogenous, in their organizational aspects and in their actions, leaving open and unexplained a possible explanation of the great internal variability documented for past and present societies (Binford 2001: 12).

The theoretical approaches based on *French Structuralism*, *Semiotics*, *and Cognition* frameworks, in spite of also having relative chronology as one of their main aims, they attempted a deeper kind of interpretation, trying not only to access the abovementioned "rules of grammatical visual composition" understood as a code of communication represented in parietal art but also proposed a complex explanation of symbolic character. Such explanation considered that the conceptual scheme of thought of prehistoric societies was based on dichotomies manifested in the recurrent associations of motifs which represented opposed principles of sexual nature, which identified a specific animal (horse or bison) with a specific abstract motif (lineal or figure) with a male or female principle, and which, associated to another animal, characterized with the opposed sexual character, formed a composition scheme. From this assumption they drew the conclusion of the existence of a male–female dualism in the representations, forming inextricable associations between topic and symbolism, which organized the ideological world of the Paleolithic societies. Such explanation was extremely criticized a posteriori, and due to this the interpretation about animal-sign sexual dichotomy was abandoned. Afterwards some of the most interesting ideas of this framework were pinpointed as useful, such as the importance given to context, the introduction of questions about the social organization of the art producers, and the interpretation of motifs as possible ethnic markers.

Key Issues/Current Debates

The search for recurrent regularities in the archaeological record, be it of artifacts, of designs, and/or structure features, remains the basis of archaeological research. On the grounds of such regularities, "categories," "types," "styles," "classes," and many other categories used to "order" the apparent "chaos" in the past material record have been developed and used. In fact, as Gnecco and Langebaek (2006) state, such a kind of "organizing" thought, which they term "typological thought," is our guide, a lense through which we

categorize the world around us (plants, peers, emotions, etc.), but although we cannot live without "typological thought," we can in fact escape from its tyranny. These authors (Gnecco and Langebaek 2006) understand "tyranny" as the inherent limitation to reduce the great world variability to manageable and narrow proportions, and they propose that to escape from such tyranny, it is necessary to:

(a) Accept that the already constructed typologies order the world does not mean that the world only fits in them and that we cannot invent new categories, new ways of interpretation, new analytical avenues.
(b) Remember that typologies have an unnecessary tendency towards universalization, which the scientific abuse of typologies gave them a universal character which is not part of their definition, given that typologies are only universal if the theory that builds them needs them to be.
(c) Understand that the typological tyranny essentializes and is ahistoric because it empties all categories of time and space.
(d) Recognize that typologies, as any other social product, do not escape from ideological struggle, and, for this reason, they are not neutral constructions but power mechanisms. In this sense, typological reasoning is, also, a political theory.

In respect of this latter point, the example proposed by Gnecco and Langebaek (2006) is very clear, since they stress that the bases for evolutionism were established on social typologies (savagery, barbarism, civilization) which translate cultural differences into temporal hierarchies, while such hierarchies supported the ideology on which the European colonial expansion was based during the nineteenth century. Hence, such process converted social typologies not in disciplinary findings but in mechanisms of colonial domination whose typological tyranny is hidden with arguments of objective neutrality.

These authors also assert that, in fact, the generalization of typological thought appears almost next to the formal origin of archaeology as a discipline and coincides historically with the formation of the nation-states and the nineteenth-century colonial expansion, which fostered ideologically the classical evolutionism which held the existence of cultural hierarchies. Later, following the same perspective, towards the 1960s, archaeological theory adopted neo-evolutionist typologies about society, which have had a great importance in the interpretations of the human social past. In fact, these have been used in a prescriptive manner, leading the archaeologists to be more interested in "confirming" the existence of types from a few cultural traces than to try to develop imaginative interpretations, sensitive to local contexts, inquiring into different dimensions of social life. Thus the tyranny of typological thought has reduced the interpretive spectrum in a dramatic manner (Gnecco and Langebaek 2006: ix-x).

For these reasons, the cited authors propose that, although typologies are inevitable (since they create nets of meaning in which symbols make sense), their "tyranny" can be faced in archaeological practice if they are used from a *critical*, *heuristic* perspective (as means to reach alternative and suggestive interpretations and not as ultimate and definitive ends) and not in a *prescriptive* manner (instead of using them as threads that need to be followed, they have to be used as constitutive parts of complex and connective weaves) (Gnecco and Langebaek 2006: ix-x).

International Perspectives and Future Directions

Following the considerations done by the previously cited authors, it can be said that it is important to (a) discern *recurrent patterns* in the archaeological record and (b) be *cautious* and have *ample criteria* when proposing interpretations about them.

In fact, the existence of regularities in the archaeological record, be they defined as "artifact types," "patterns of element associations," "recurrent features," etc., are the tip of the iceberg to make complex questions about past societies. The way in which these questions are asked and the

ways designed to answer them will be the key to their success or failure when applying them as a significant research method.

With the archaeology of art, this is particularly important given that graphic designs offer a wide range of interpretive possibilities. In fact, beyond the abuses committed in terms of establishing "styles" in the traditional manner when studying portable art or rock art in different parts of the world, a wider approach to the analysis of these very same items can allow to ask more complex and varied questions about the societies that produced them.

To do so, it is important to open lines of inquiry that take into account "variability" at the time to interpret regularities observed in the archaeological record and its changes, searching for causal factors among them. In this sense the analysis of variability must always have three basic instances: (a) temporal variation (different chronology), (b) spatial variation (different society), and (c) intra-society variation (different function/s). This is applicable both to portable art and rock art, but they do require different approaches.

In effect, portable art has the same features than any other artifact, with the addition of bearing graphic representations. Therefore it can be analyzed with the same methods applied to study the archaeological record in general, adding some specific strategies to analyze its designs.

Rock art, instead, is different because the plastic representations have been made on top of natural media, without any "object" or artifact to bear them. This situation has led rock art to be left aside from archaeological research (mainly in the North American school), particularly because given it is not embedded in a sedimentary matrix, its relative chronological ascription was very difficult, and, until recently, its absolute dating was impossible; otherwise, it was studied from non-archaeological approaches but recurring to other disciplines (fundamentally in Europe, such as in France and Spain).

However, in other countries, interesting archaeological approaches to rock art have been developed. It is interesting to mention here that such countries are not central places in terms of archaeological theory and/or method development, and among them it is worth mentioning the cases of Australia and Argentina. Australia has greatly contributed to the development of "informed methods" (sensu Chippindale and Nash 2004), following the great number of works carried out in areas where Aboriginal communities still have direct links to the production – use – meaning of rock art. Argentina, in turn, has developed more in relation to the "formal methods" (sensu Chippindale and Nash 2004).

In effect, Gradin (1978) proposed an integral method for rock art analysis that attempts to differentiate rock art production in particular regions (space), through an archaeological sequence (time) and in correlation with different human groups (culture). Such an approach considers that rock art has to be studied at regional scale, articulating information from excavated sites and from rock art sites. He proposes the consideration of three fundamental aspects in rock art analysis:

(a) Topography: *spatial* location (position, accessibility, visibility, specific rock surfaces selection, etc.)
(b) Representation: rock art production processes as *material culture* (topic selection, graphic mode in which it is produced, techniques, etc.)
(c) Chronology: its position in the regional archaeological sequence (superimpositions, fallen rocks with rock art contained in datable sediments, etc.) to assess their consecutive production through time

With these criteria he developed analytical units (motifs, stylistic groups, stylistic modalities, etc.), and their presence-absence observation, spatial or temporal recurrence, etc., allowed him to establish rock art sequences in Argentinean Patagonia. His model was applied by other authors to specific areas of Northwest Argentina.

In spite of the fact that this methodology, which is very useful to establish regional sequences, focuses mainly on temporal variability (a common situation in most part of archaeological typologies), its usefulness can be significantly widened if it is complemented by other approaches.

Rock art taphonomy (sensu Chippindale and Nash 2004) points out that "differential survival" of rock art images is a critical issue. This variable, however, presents serious difficulties when trying to estimate "comparative arts of survival" required to estimate the postdepositional processes – via natural or human agents – which could affect rock art at the scale of motif, site, area, or region. For this reason, it is important to take into account:

A. When analyzing the incidence of *natural processes*, assess:
   (a) The possibility of complete destruction of sites due to causes such as mass erosion or redeposition, typical of specific geological processes
   (b) The state of conservation of sites with current archaeological visibility, considering:
      1. Bedrock composition, surface processes (exfoliation, biotic growth, accretions, etc.)
      2. Degree of exposure to natural mechanical weathering agents (solar, wind, rain erosion, etc.)
      3. Features of the bedrock protection (e.g., drip line)
      4. Cardinal orientation of the site
      5. Natural agents acting locally and extension of their potential or real damage, among many other factors
B. When analyzing the incidence of human agents, conceived as the actions carried out after the production of rock art representations at a given moment of the sequence, it is important to assess:
   1. The production of new motifs superimposed to others previously made
   2. Events of repainting or reengraving
   3. Use of part of previous motifs to create new ones
   4. Premeditated total or partial destruction
   5. Total or partial cover with sediment or constructions product of later uses of the site

Rock art functions entail that the causal factors due to which rock art representations were created are fundamental variables to be assessed during research.

A-As noted above, the focus placed in the chronological appreciation of rock art resulted, in most cases, in the consideration that observed variation in a specific attribute ("type") assemblage was considered to have been caused by changes through time. This has been detrimental to the assessment of functional variation in rock art production.

B-Functional variation is understood as the diversity of representations that may have been made by the same society in a single moment of the sequence, due to different factors and for different purposes (sacred sites vs. domestic sites; male sites vs. female sites; territorial marks vs. aggregation sites, among many other possibilities). To assess the possible function that specific rock art representations may have had is critical at the moment of proposing interpretive approaches to it.

Both the considerations about *taphonomy* and about *function* are intimately connected with the considerations about *chronology*. In fact, to attempt the inference of a relative production sequence of rock art in a specific region, it is essential to assess both the possible differential occurrence of rock art due to postdepositional variables, as much as the existence of diverse types of rock art representations due to functional variables in specific chronological segments. Such interconnection is so vital that an erroneous assessment of any of these variables can lead to an erroneous estimation of the others.

Taking this into account, the construction of regional relative sequences becomes more complex since it not only requires the consideration of more variables but also of more research questions. Nevertheless, their construction is still a fundamental tool for rock art studies since it is a key to frame rock art in time and space, in order to articulate them with the general regional archaeological sequence.

Nowadays, even counting in some cases with the possibility of obtaining absolute dates with AMS, it is crucial to count first with a well-established relative sequence, given that this

sequence is the guide to the sampling process to date specific relevant motifs within such sequence. This procedure reduces the number of samples to date (avoiding unnecessary destruction), increases the strategy efficiency (covering the whole sequence and/or functional variables), and saves time and economic and professional resources.

Thus, the importance given the development of *regional rock art sequences*, taking into account all the mentioned variables, makes it possible to answer more complex research questions, thus putting the evidence provided by the archaeology of art in a privileged place within the regional studies of past societies.

Introduction

Around 100,000 BP (before present), a new class of artifacts began to appear at archaeological sites in Africa and the Middle East. These items included pierced marine shells probably worn as personal adornment (e.g., Qafzeh, Israel; Oued Djebbana, Algeria) as well as pieces of bone and ochre that display deliberate nonfigurative markings (e.g., Klasies, South Africa; Pinnacle Point, South Africa; Blombos, South Africa). Additionally, the presence of red ochre and related materials to prepare this pigment (e.g., Blombos, South Africa) is present in Africa and the Middle East with evidence of ochre color curation dating back further to 200,000 BP and possibly even beyond (e.g., Saï Island, Sudan; Twin Rivers, Zambia). These artifacts are often cited as the earliest evidence for the "creative explosion" associated with the *Homo sapiens* species, but until 40,000 BP, these potential examples of symbolic behavior remain infrequent and confined to portable objects. Around 40,000–60,000 BP, the frequency of symbolic artifacts increases. This is correlated with the spread of modern humans across the Old World. Around this time, rock art and sculptural art emerged. Paleolithic art is generally divided into three main categories:

1. Parietal art: Also known as rock art, this category includes all paintings, engravings, drawings, and stencils (Davidson 1997: 125) found on immovable surfaces such as the walls, floors, and ceilings of rock shelters and caves. There is also some evidence in Europe of parietal art having been created in open-air settings (e.g., the engravings at Fornols-Haut in France and the Côa River Valley in Portugal). Due to taphonomic processes such as wind and rain, these outdoor decorated locations have generally not survived.

   The majority of the paintings were done with either red or black paint, most commonly produced using red ochre and charcoal, respectively. However, there are also some sites where the mineral manganese oxide was used to create the black color. Other less common colors include yellow, purple, and brown (also derived from ochre), and in rare instances white paintings made using kaolin clay have been identified. Preparation was required to produce the paints, including the grinding of the pigments and the use of formulas created by mixing the color component with binders (e.g., water, urine, animal fat) and extenders (e.g., feldspar, biotite, talc, clay). Engravings were done using either a tool to mark the stone, or in cases where the surface included softer materials such as clay, a finger was sometimes used to create the image. The creation of drawings involves the use of dry material in the form of ochre crayons or charcoal sticks as opposed to the use of liquid paint formulas. Stencils refer primarily to the creation of negative hands, which were produced by a method known as spit painting, where the paint or raw pigments were blown over a hand placed against the surface in order to leave an outline.
2. Portable art: This subcategory includes all portable artifacts found at Paleolithic sites that incorporate a symbolic or artistic element. This includes everything from weapons or tools that have been embellished or decorated (e.g., atlatls) to plaques or pebbles that have been painted or engraved as well as the large number of figurines that have been found at sites across Europasia. The materials used to make these portable objects include but are not limited to stone, bone, antler, ivory, and clay.
3. Personal adornment: Most of these pieces are found in elaborated burials and appear to have been worn as jewelry. These artifacts are differentiated from the portable art by being items specifically produced to adorn the human body in some manner. The most common materials used to make these ornaments are pierced teeth, marine shells, ivory, and bone. Large numbers of ivory beads have also been recovered, many of which bear evidence of having been sewn onto clothing and headwear (e.g., the three elaborate burials from an Upper Paleolithic site in Sungir, Russia).

Paleolithic images are generally divided into two categories: figurative imagery, which is defined as identifiable art and most often refers to animal and human depictions, and nonfigurative imagery, which includes all abstract or geometric images not easily identifiable as being real-world objects or entities. One type of imagery that appears to be absent at nearly all rock art sites older than 10,000 BP is landscape (e.g., trees, mountains, or rivers) as well as images of everyday life including structures such as housing (but see Utrilla et al. 2009, mountains and water features; Garcia-Diez and Vaquero 2015, huts and campsites). Even though the art found in different global regions is varied, there are several overarching themes that are identifiable at sites worldwide:

1. Animal imagery: While the specific subject matter might be determined by the environment in which the art is being produced (e.g., mammoths in Europe, kangaroos in Australia, eland in South Africa), the inclusion of animal imagery at rock art sites and on portable objects is almost universal. At Paleolithic rock art sites across Europe, animal imagery is usually the dominant theme (e.g., horse, bison, mammoth, ibex, deer), and many of the portable art pieces also include animals in their decoration.
2. Human imagery: Images of humans whether they are accurate depictions or more stylized representations are also found at rock art sites globally. In some cases, these representations have been categorized as being therianthropic,

Art, Paleolithic, Fig. 1 Megaloceros, ibex, and human with protruding spears – Cougnac, France. (Photo by J. Clottes)

appearing to portray a human-animal hybrid (e.g., the sorcerer at Les Trois-Freres, France). They are also found occasionally on portable objects. In Europe in particular, there is an entire collection of human figurines from the Paleolithic period (see discussion about these figurines in the "How Old Is the Art?" section). The inclusion of human images at rock art sites varies widely between regions, with them being fairly unusual at European sites but more common at contemporaneous sites in Australia.

3. Abstract imagery: Also known as geometric signs, these images include everything from simple dots and lines to more complex geometric shapes such as tectiforms or scalariforms (see Fig. 1). Geometric signs are found at rock art sites around the world, and in regions such as Europe, these abstract images outnumber the figurative representations at most Paleolithic sites (Bahn and Vertut 1997: 166). These markings are also found on many portable art objects, including items of personal adornment. While this category is often defined as including all images that are not recognizable as items from the mundane world, it has been argued that some of these markings could in fact represent weapons, tools, or other physical manifestations of human behavior (Figs. 2, 3, and 4).
4. Hand imagery: This is ubiquitous in rock art and includes negative hand stencils, positive handprints, and stylized hands. Negative hand stencils are created when a hand is placed against a flat surface such as a cave wall and pigment is blown around it. When the hand is

Art, Paleolithic, Fig. 3 Panel of geometric signs – Niaux, France. (Photo by J. Clottes)

Art, Paleolithic, Fig. 4 Panel of hand stencils – Gargas, France. (Photo by J. Clottes)

removed, a negative outline of the hand remains. Positive handprints are created when pigment is applied directly to the palm and the fingers of the hand, and the hand is then placed against a flat surface. Stylized hands are free-hand drawings which often include abstract images. Hand imagery is subdivided into its own category as it cannot be presupposed that the intention of the Paleolithic artist was to reduce the representation of a human to a handprint or that a handprint could represent an entire human.

Definition

In its broadest sense, the term Paleolithic art encompasses all deliberately modified surfaces and artifacts created prior to 10,000 BP that were thought to have been produced with symbolic intent. Traditionally Paleolithic art has been identified with symbolic artifacts and images found at archaeological sites from the Upper Paleolithic period in Europe, dating roughly to between 10,000 and 40,000 BP. However, this expression is also sometimes used as a blanket term to refer to all parietal art, portable art, and personal adornment found globally and dated before the end of the Pleistocene period (before 10,000 BP). This art is generally associated with modern humans, though there are several artifacts from Europe that have been identified as being produced by Neanderthals (e.g., a necklace from the French site of

Arcy-sur-Cure). There has even been recent speculation that some of the oldest art may have been created by Neanderthals, though this remains to be proven.

Historical Background

The discovery and acceptance of Paleolithic art was a gradual process that took place over the course of the nineteenth century. Beginning in the 1820s, portable art objects started being excavated at sites across Europe. Some of the earliest discoveries were in France, where they were believed to be of Celtic origin. It was not until the 1860s that the notion of these artifacts being from the Ice Age was proposed. This was partially due to a greater acceptance of geological chronologies of the earth, as well as discoveries of these objects in archaeological layers with ancient tools and extinct animal species (Bahn and Vertut 1997: 14).

While the recognition and incorporation of portable artifacts and items of personal adornment into the archaeological literature was fairly straightforward, the same cannot be said for the parietal art. The idea that art of this caliber could have been made by such "primitive savages" was hard for many of the Paleolithic archaeologists of the nineteenth century to accept, and it was not until the very end of the 1800s that parietal art was officially incorporated into the category of Paleolithic art (Bahn and Vertut 1997: 20). For example, in 1878 some wall engravings covered in calcite were noted at the site of Chabot in France along with the discovery of Paleolithic tools. While these were thought to be prehistoric in origin, the concept of this behavior being a regular occurrence took much longer to be accepted and was for the meantime ignored. At that time, Paleolithic archaeologists refused to believe that the bison paintings on the ceiling of Altamira in Spain, first discovered in 1879, could have been made by ancient humans due to their level of sophistication. However, as more and more parietal art was discovered, including sites where the images on portable art objects matched those on the walls, scholars finally came to accept the age of the art. By the early 1900s, many studies had been initiated to investigate this phenomenon further.

Key Issues/Current Debates

How Old Is the Art?

As previously mentioned, deciding which objects should be incorporated into the category of Paleolithic art was problematic in the past and is still a source of contention today. In fact, the term "Paleolithic" refers to tool industries found only in Europe, not those of Africa, Asia, or Australia. For this reason, many archaeologists prefer to use the term Pleistocene art. Instead of referring to archaeological materials from a particular region, the Pleistocene is a worldwide geological epoch that coincides with the last Ice Age and is thus a more inclusive term. The Pleistocene begins around 1.75 million years ago and ends around 10,000 years before the present. The emergence of art varies across the globe but becomes abundant in the Old World around 40,000 years ago.

Africa: The earliest images from Africa come from the cape of South Africa in the form of abstract markings on different mediums. Engraved bones are present at Blombos Cave and Klasies River Caves. Engraved ochre is also present at Blombos Cave. The previously mentioned objects all date to between 70,000 and 100,000 years ago. Around 80,000 BP, inscribed ostrich eggshells are present at sites such as Diepkloof Rock shelter. These objects were created during a period known as the Middle Stone Age (MSA). The MSA is preceded by the Early Stone Age and is followed by the Late Stone Age. Objects from the Middle Stone Age have been notoriously difficult to date as radiocarbon dating only extends to 40,000 years, and potassium/argon dating cannot be used on materials younger than 500,000 years old (McBrearty and Brooks 2000). Therefore, depending on the context, detailed stratigraphic knowledge must be combined with other dating methods such as argon/argon, infrared-stimulated luminescence, thermoluminescence, or optically stimulated luminescence. Figurative images are

present on ochre slabs at Apollo 11, in Namibia and Nswatugi, Zimbabwe, and date to the late MSA, around 27,000–25,000 years ago. Pleistocene imagery may have an earlier origin, as ochre "pencils" were discovered at Klasies River dating to over 100,000 years and at Howiesons Poort to 65–80 ka. Hematite "pencils" have been dated to 100,000+ years at Border Cave, South Africa. Unfortunately, unlike Europe, Africa lacks large limestone caves that have favorable conditions for preserving rock art (McBrearty and Brooks 2000).

Australia: Pleistocene art in Australia is difficult to date as much of the imagery was created using ochre in open-air settings. At present, archaeologists are only able to date charcoal and cannot directly date ochre. Additionally, charcoal is more susceptible to weathering in open-air environments. It is also challenging to numerically date engravings on a rock in contrast to objects that have been buried. Images in Australian art are diverse and include geometric signs, animals, humans, finger fluting, handprints, and chimeras. The oldest "art" in Australia comes in the form of cupules, circular depressions that are created on a rock surface. Cupules at Pilbara Northern Queensland, Turtle Rock, and Sandy Creek are thought to be at least 30,000 years old (Bednarik 2010). Early animal depictions in Kimberly region are believed to be 40,000 years old. In terms of geometric forms, circular shapes on a bolder in Spear Hill/Abydos are dated to 20,000–27,000 years ago with older symbols found in the surrounding vicinity (Bednarik 2010). Finger fluting at the Gallus site dates to at least 20,000 years. While much of the parietal art is difficult to date, relative chronologies have placed the artwork in a late Pleistocene/early Holocene time frame.

Asia: As in Australia, cupules are arguably the oldest "art" found in Asia. In India, at Auditorium Cave a cupule with a line running along part of the edge was dated to the "Acheulian" (Bednarik 1994). Recently numerous hand stencils and two animal depictions were discovered across seven caves sites in Sulawesi, Indonesia (Aubert et al. 2014). One of the handprints was dated to 39,900 years ago, making it the oldest hand stencil in the world. Also on Sulawesi, an artifact that was used to produce standardized beads, bone pendants, ochre, and incised stone artifacts were recovered dating back to 30,000–22,000 years ago (Brumm et al. 2017). Both of these recent discoveries question the notion that Europe was the center of artistic development for our species.

As in other regions, statuettes and two-dimensional images were also created. An ostrich eggshell with engravings was found at Patna, India, and dated to 25,000 years before present. Beads were created from a variety of mediums including shells, pebbles, as well as deer and fox teeth at the Upper Cave of Zhoukoudian. These materials date to 13,000–18,000 years BP (Bednarik 2013). Perforated shell beads were found associated with a burial at Qafzeh Israel dating to around 92,000 years ago. However, the objects that have received the most attention are the anthropomorphic and animal figurines from Mal'ta and Buret', Siberia. These diverse ivory figurines date to around 23,000 years old. Recently, a shell tool with a geometric engraving was reanalyzed and argued to be created by *Homo erectus*. While it is unclear as to whether the engraving was used for abstract, functional, communication, or another purpose, it does make us question whether *Homo sapiens* were the only species capable of creating art.

Europe: The Paleolithic of Europe can be divided into three major subdivisions, lower, middle, and upper. Both parietal and portable art emerge in Europe during the Upper Paleolithic. Specifically, the oldest rock art and figurines date to the Aurignacian industry, which begins in Europe approximately 40,000 years ago. Common subjects include negative hands, geometric signs, and animals. Depictions of humans in European rock art are relatively rare, and animals such as horses, bison, and mammoths dominate cave walls. Although personal adornments are widespread by the Aurignacian, some archaeologists have argued that the ornaments from Grotte du Renne were created by Neanderthals in the Chatelperronian (for a critical view on this topic, see Higham et al. 2010). Two recently discovered images have also been associated with

Neanderthals. One is an engraving from a cave in the Gibraltar region that resembles a tic-tac-toe symbol. The other is an image of what may represent seals found in a cave in Malaga, Spain. While paleoanthropologists acknowledge that Neanderthals were in these areas when the images were created, it is less certain as to whether *Homo sapiens* were also in the region at the same time. In regard to portable art, with the exception of the "Venus" of Hohle Fels and the "Venus" of Galgenberg, all of the Aurignacian figurines are of animals. Starting with the Gravettian, an abundance of predominately female anthropomorphic figurines becomes widespread across Europe. Male figurines and those that lack secondary sexual characteristics can be found in collections at the following sites: Mal'ta, Kostenki I, and Dolní Věstonice. The anthropomorphic statuettes vary in size, material used, body position, stylistic features, and contextual details. The female figurines are commonly referred to as "mother goddesses" or "earth mothers," although evidence of a shared belief system has not been corroborated. Animal figurines were still created during the Gravettian and are found in abundance at Dolní Věstonice, Pavlov, Predmostí, Petrkovice, and Kostenki I, often in conjunction with female figurines (Bahn and Vertut 1997). Both animal and anthropomorphic statuettes continue to be created in the Magdalenian but become less realistic and instead are more stylized.

Who Made the Art?

The early interpretations of Paleolithic art reflected an androcentric bias in archaeology. It was commonplace to assume that the art had been made by men and small boys. One of the most prevalent of these interpretations focused on a male shaman producing rock art while in a trance. According to Bednarik (2008: 173), the shamanistic or totemistic interpretation of the rock art has remained popular theoretically because such interpretations add a greater "perceived value" or "worth" to the artwork. However, neither of these theoretical interpretations are scientifically testable, and the perpetuation of these androcentric interpretations further promotes an unsubstantiated bias in archaeology today (Sharpe and Van Gelder 2009: 324). A more current interpretation acknowledges that Paleolithic art was created by both males and females of varying ages. Preliminary studies employing the 2D/4D ratio (second to fourth digit) to determine sex from hand stencils have done so with a reasonable degree of probability. In addition, the presence of small handprints and footprints in caves such as Chauvet and Cosquer in France makes it apparent that children were present and active within the caves as well. Regardless of age or sex, all of these interpretations have assumed that Paleolithic art was the product of anatomically modern humans alone. However, new uranium-series disequilibrium dates taken from calcite deposits overlying or underlying art found at a series of Spanish caves, most notably El Castillo, have turned this assumption on its head. With dates of up to 40,000 years, these finds suggest that Neanderthals could have also engaged in cave painting, but with modern humans already being in Europe by this time, it is difficult to determine who may have been the first parietal artists (Pike et al. 2012).

However, multiple personal adornments, colorants, and decorated bone tools were discovered in Châtelperronian levels at Grotte du Renne, Arcy-sur-Cure, France. This suggests that even if Neanderthals were not making cave art or mobile art, they were engaging in different artistic behaviors.

Why Did They Do the Art?

Since the discovery of the first portable and parietal art in Europe in the late 1800s, researchers have tried to understand why Paleolithic artists engaged in this behavior. "Art for art's sake" was a prominent theory of the nineteenth century referring to the belief that Paleolithic art had been created for decorative and aesthetic purposes only, but this hypothesis has now largely been abandoned. Early functionalist theory relied heavily on ethnographies of "primitive" societies and correlating the need for food back to the

images on the cave walls. The functionalist approach includes:

1. Hunting magic: This hypothesis was derived from ethnographies of modern hunter/gatherers who hunted with stone tools and produced rock art in order to enhance the success of their hunt. Animal imagery which includes "missiles," blood, and/or wounds has been used to support this theory. Other nonfigurative images have been interpreted as tracks and droppings to corroborate the theory that animal imagery was produced as a means of transmitting hunting knowledge.
2. Sympathetic magic: Like a "voodoo" doll, this hypothesis relies on the concept that animals depicted in rock art influence animals in reality.
3. Fertility magic: This hypothesis was based on the discovery of pregnant and/or copulating imagery including the "precopulatory bison" of Tuc d'Audoubert, France, and the numerous "Venus" figurines.
4. Trophyism: This asserts that hunting was done as much out of necessity as it was to impress females. Animal imagery was produced by a male to impress a female with his hunting abilities and to ultimately increase his reproductive success.
5. Shamanism: This relies on the concept of a male shaman producing rock art while in a trance. Purported examples of shamanism in rock art include the "leaping cow" from Lascaux, France; the "sorcerer" from Les Trois-Freres, France; and the mammoth ivory half-man, half-lion figurine from Hohlenstein-Stadel, Germany.

Along with the above theories of meaning, there are also several major theoretical approaches that have been employed in the study of Paleolithic art; these include:

1. The *structuralist* movement was inspired by the linguistic works of Ferdinand de Saussure and first brought to popularity by the French anthropologist Claude Levi-Strauss. This approach rejected the "straight-line" development of art from simple to complex and from abstract to naturalistic. The creation of images were not unique artistic events, images were intentionally selected for by species type or abstract design, and they were created in specific locations within a particular site, in deliberate association to other images. Two of the main proponents of this approach within the field of Paleolithic art were Andre Leroi-Gourhan and Annette Laming-Emperaire.
2. Settlement archaeology developed out of the *processualist* movement and involved the study of the spatial distribution of human activities and particular occupations within a single room, house, overall site, or region where landscapes were passive backdrops. The focus was on demography, technology, how people used the land, and how the land constrained the people.
3. The *post-processualist* movement involves examining the social aspects, such as the material connection to the land and the human interaction with the land. Within this theoretical framework, there are three main ways that researchers have chosen to approach the art:
   1. Archaeology of place: Landscape was active and complex and recognized that cultural heritage was shaped through tradition and memory. People, places, and features are considered integral, and landscape is seen as shaping and being shaped by human experience.
   2. Social geography: This relies on the idea that Paleolithic peoples moved in and through the landscape and that a regional scale of analysis was required. While "meaning" may be culturally specific, the phenomenological approach or the conscious human experience of everyday life allows scholars to approach landscape and built locations, such as painted caves, as they were perceived, represented, and experienced by Paleolithic peoples.
   3. Pleistocene visual culture (Soffer and Conkey 1997): This relies on the argument

that Paleolithic imagery is about materiality, meaning making, and recognizing that Paleolithic peoples were active, social agents in constructing their world (Conkey 2009). The images they produced, in terms of materials, colors, shapes, placement, and association, are all part of creating meaning and are therefore integral to the larger picture.

Prehistoric Pornography?

As has been previously mentioned, the idea that adolescent boys created Paleolithic imagery may have influenced Guthrie's (2006) idea that the female statuettes and bas-reliefs were a form of prehistoric pornography. He argued that the mostly "naked" statuettes shared similar body proportions having small waists and broad hips; this is referred to as having a low waist-to-hip ratio. This body type is considered beautiful cross-culturally and is also linked with fertility and overall health in females (Zaadstra et al. 1993; Singh and Singh 2006). However, upon analysis of the actual statuettes, Tripp and Schmidt (2013) found that the figurines actually share a high-average waist-to-hip ratio. This body type is not seen as attractive in modern populations and is linked to infertility and several mental and physical health conditions. Overall, the amount of diversity among the figurines in terms of style, contextual details, and materials makes it difficult to find a single explanation that can explain the earliest anthropomorphic art.

Art as Communication

Beyond its aesthetic properties, art can also be seen as a type of visual communication system as it is composed of graphic marks, many of which carry culturally agreed upon meanings. It is likely that experimentation with visual marks during the Pleistocene paved the way for the later development of writing. While the meanings of these early images remain elusive due to the time depth and lack of living informants, art is often used to educate; to record information about seasonal, historic, or ritual events; and to claim ownership of places or objects, as well as sometimes signaling individual identity or group membership. While all Paleolithic art potentially has this capacity, many of the geometric signs have specific usage patterns that point to there being a specific purpose and intention in their inclusion by the artist (von Petzinger 2016). Additionally, in a recent cladistics analysis, Tripp (2016) found evidence of numerous intentional stylistic similarities among anthropomorphic "Venus" figurines from various Russian Plains Gravettian sites, suggesting that there were shared art-making traditions as well as communication between the sites.

International Perspectives

At present, there is no one international means of rock art tourism and conservation, but rather, such decisions are made at each country's discretion. As a result, there is differential preservation of rock art around the world. In 1970, UNESCO created a set of guidelines for cultural tourism management and the preservation of World Heritage Sites with the intent to balance conservation efforts with providing cultural tourists with a meaningful experience through public education. South Africa's rock art sites receive around 240 million "cultural tourists" a year, and in consequence, the rock art is caught between the competing interests of impact assessors, who are concerned with the conservation, ethics, and ownership of the art, and those involved in the commodification, pricing, and promotion of the rock art as tourist attractions (Deacon 2006). The Dampier Archipelago of Australia contains the largest concentration of rock art in the world with an estimated million petroglyphs associated with other archaeological materials, such as shell middens and quarries. However, the archipelago has been threatened by years of development and industrialization, and it has led to the slow degradation of the rock art and the destruction of the cultural heritage over time (Mulvaney 2011). In 2007, the rock art paintings of the Sierra de San Francisco canyons of Baja California Sur, Mexico, were threatened despite the fact that they were on the UNESCO World Heritage List. Development of the land, in particular the plan to build roads through the canyons to create ease of access, threatened the art that had long been protected by

its remoteness, the need for mules, and local guidance (Clottes 2008). In France, Lascaux Cave has long been endangered through the proliferation of a fungus initially brought on by the influx of tourists after the cave was first discovered. To save the art at Lascaux and Altamira in Spain, replicas of the caves were built which are open to the public. At other caves, controlled visitations, digital recordings, photographic archiving, and the production of virtual cave tours have all contributed to the preservation of the art. In all instances of rock art conservation, however, it is critical that we bear in mind that the greatest threat to the art is human in origin and that it is predominantly due to ignorance and a lack of interest (Clottes 2008).

Future Directions

Future directions in the study of Paleolithic art include incorporating theoretical background with innovative scientific techniques. Tosello and Fritz (2007), for example, experimented with a 3D scanner to record the imagery found on cave walls. This technology allows researchers the ability to record images in more precise detail. Investigators, for example, are able to scan images and screen out modern graffiti, darken lines that are deteriorating, and prevent the flattening of 3D images. They were also able to use this technology to analyze individual brushstrokes of two rhinoceros on the panel of horses in Chauvet Cave. Their results allowed them to make inferences about the intention, skill levels, and cognitive processes of the artist.

Since the antiquity of rock art was first proposed in Europe during the late 1800s, this continent, and in particular its western region, has held a preeminent place in the discipline. Europe has often been the benchmark against which other rock art is compared both in terms of stylistic analysis and temporal sequencing due to the existing chronology of direct and indirect dates that have been collected from rock art sites. As interest and funding are directed toward the parietal art found in other parts of the world, this is beginning to challenge the assumption that the oldest art in the world is from W. Europe. Additionally, as dating methods improve, this will allow researchers to pursue more precise questions. As the many examples cited in this entry show, there are in fact sites from the Paleolithic period around the globe, and as new dating techniques are applied at these locations, we may find that the time line for the origins and dispersal of this behavior will need to be completely rewritten.

Art, Types of

Mireia López-Bertran
Departament d'Història de l'Art. Facultat de Geografia i Història, Universitat de València, Valencia, Spain

Introduction/Historical Background

The major classification of types of art from the traditional perspective of art history is based on

three main types: visual arts, applied arts, and performing arts. However, this classification has been created by scholars devoted to the study of art from a modern and Western point of view and is based on the idea of expressing individual values and skills inside a network that commodifies artistic creations (Corbey et al. 2004: 357–362). As all classification attempts, this definition does not fit perfectly into the study of arts on other places or from all times. Indeed, there is a long discussion regarding the definition of art from an archaeological point of view.

Keeping in mind that both, art history and archaeology, were born as academic disciplines during the eighteenth century, it is worth mentioning how the two disciplines have approached and understood artworks since then. Generally speaking, Western societies have had a definition of prehistoric, indigenous, or ancient arts based on the projection of the concepts which structure our modern system of art. This is certainly created during the eighteenth century when the concept of art was divided into two main types: "fine arts" and "crafts" or "popular arts" (Shiner 2001: 3–5). All the artworks recovered from archaeological or ethnographical record were labelled within the latter definition. Since then, many conceptual debates and theoretical foundations have classified and approached art (see Fiore 2014 for the review of the theoretical frameworks). One of the major concerns is to define what makes an archaeological material to be defined as art. A basic starting point to deal with this topic is to remind that in many occasions we describe specific material culture as art for convenience only and it is generally agreed that people who created what we labelled as "artworks" as well as the people who subsequently viewed them throughout time never thought of them in this way (Corbey et al. 2004; Chippindale and Taçon 2006 among others).

Definition

Categorizing artworks recovered from archaeological fieldwork is a challenge. Studies of the "archaeologies of art" are deeply fragmented by period, medium or scholarly tradition creating fuzzy boundaries to write a concise definition. For instance, Prehistoric European art has been studied from a regional, stylistical, and chronological point of view (see Robb 2015), whereas ethnoarchaeological research undertook in Africa or Australia (Ouzman 2005; Domingo et al. 2017) not only deals with these issues but also pays special attention to cultural sensibilities and ethics due to their work with indigenous communities and their material culture and ideologies.

Which are the features to define specific material culture as artistic pieces? One can defend that archaeological and ethnoarchaeological artworks might have some degree of visual impact; they are somehow distinct from others often indicated by the time, effort, skill, and imagination put in their making and present some patterns in their form or decoration which communicate beliefs, values, or affective meaning. In addition, such works are often aesthetically pleasing to their makers (Corbey et al. 2004: 361–362). Interestingly, aesthetics in archaeology has been challenging the preeminence not only of the visual in art research but also has widened its definition by introducing materials of everyday life like cooking pots or weapons that according to our modern eye are not defined as art and if so are closely related to crafts rather than fine arts. This is nicely illustrated by the study of J. Coote (1992) that demonstrates how cattle is the primary aesthetic locus for African Nilotic societies instead of any art piece. In the same vein, the material culture perspective is an inclusive methodology that focuses on how artworks are agential and have to be seen in terms of their participation, engagement, and actions, rather than simply as objects and images to be passively viewed (Gell 1998; De Marrais and Robb 2013).

With this premise in mind, a basic division between types of art can be between visual arts, focused on art-object research, and performative ones, centered on activities undertook whether by their creators or their participants. The most famous arts of this kind are dance and music. It is generally agreed the preeminence of visual perception in dealing with artworks, especially in

visual arts. However, recent studies advocate for multisensory experiences to engage with arts and introduce the aural, kinetic, and haptic sensations when creating, using, and perceiving artistic creations (Gosden 2001; Hamilakis 2013).

Regarding visual arts, four main types can be presented, keeping into consideration the support onto which artifacts are manufactured: fixed art, portable art, architectural art, and body art. Every type of art can be categorized into other subtypes: as a matter of guide, fixed art is divided into cave art or open-air art; portable art is divided into ornamental artworks or decorated vessels; architectural art can encompass palaces, tombs, or ceremonial buildings; finally, body art can be divided into permanent and ephemeral. Furthermore, these typologies present common features in terms of technique. For instance, engravings or paintings can be associated to more of the one type mentioned above: on a rock, on the body, or on a wall of a building.

All types of art can be scrutinized from a formal point of view. Relevant issues to be considered are the materials, the shape and size of the artifacts, or their dimensionality (2D or 3D). Other formal issues are color, texture, symmetry, harmony, and the distribution and pattern, if any, of the decorative motifs.

Considering that all types of art have some link with a referent, several categories to define an artwork are created. In a first typological attempt, images can be representative and nonrepresentative. Inside the representative, two kinds are distinguished according to the relation that the image have with the represented. On the one hand, there are the so-called figurative images, which present an iconic relation with what is represented, for example, an engraved figure that can be easily defined as a certain animal (deer, bear, etc.). On the other hand, the nonfigurative images present a link, real or imagined, with some extern referent, but the connection is not iconic. For instance, a wavy line can be interpreted as an abstract representation of a snake. Moving to the nonrepresentative images, they are always nonfigurative as they do not present a link with an external referent. Thus, they become abstract images (based on Graphic 1 from Fiore 2011: 114).

Key Issues/Examples

Beginning with fixed art, its main feature is that it is permanent in a specific place and it is normally referred to rock art, as rocks and bedrocks inside caves are the main surface. Likewise, fixed/rock art is also located on more visible or open-air supports like shelters. The techniques to decorate the surfaces are two: painted and engraved and sometimes a combination of both occurs. This art has also been labelled as landscape art because the lasting location creates a significant link between art and place, understood environmentally and socioculturally (Dobrez 2016). Besides the technique, the iconography and the style, key issues when studying rock art are twofold. On the one hand, in relation to landscape, it can be approached in terms of visibility, access, topography, and proximity to natural resources and to burials or settlements. On the other, the physical and morphological features of the rocks themselves (surface, textures, or shape) are also worth considering (David 2002). Therefore, the location of rock art is not randomly selected. A relevant case study is the painted and beeswax art from the Ingaanjalwurr rock-shelter in Western Arnhem Land. It has been demonstrated that this art is likely to have been produced during a short burst of activity incorporating the European-contact period and was used as a temporary camp on journeys between settlements. Interestingly, the beeswax and the paintings of sorcery figures have been interpreted as Aboriginal strategies to record the impact of European illnesses spreading quickly, so that these artworks materialize a moment of drastically social change (May et al. 2017).

To finish with the fixed art, recently, a more comprehensive approach that goes beyond the visual features of fixed art is being undertaken. Concretely, it refers to the acoustic properties of rocks and the creation of specific soundscapes and music (Díaz-Andreu and Mattioli 2017). It has been demonstrated that both are significant issues

when deciding the location of artwork by the artists.

The second main type of art is the "portable art" also known as "mobiliary art" because compared with the fixed art, it is easily moveable. Inside this label, two categories are identified: decorated artifacts and artifacts shaped with specific forms (Domingo Sanz et al. 2008: 15). Both categories can coexist because, for instance, a zoomorphic jug can be decorated following a specific pattern. One can distinguish between bidimensional and tridimensional too, and a wide range of materials are used. Two-dimensional drawings or carvings can be made on diverse supports like bone, stone, wood, clay, fabric, glaze, metal, or plaster. Among tridimensional objects, the figural can be also manufactured with the previous materials. Amid the modes of production stand out the handmade or mold-made. Regarding clay, the wheel-made technique is also worth mentioning, especially in relation to figurines and pottery. Portable art can be finely crafted and highly detailed, but it can also be sketchy or schematic.

Multiple categories and definitions can also be added according to the repetitive pattern whether of the object or the decorative motives. These features are useful to define styles, understood as the formal and technological characteristics of an artistic object, and can also contribute to identify artistic traditions from chronological and geographical perspectives (Domingo Sanz and Fiore 2014). Besides the aesthetic and artistic qualities of these pieces, portable or mobile artworks might also be approached by highlighting their use and functionality like decorating the body, serving food and beverages, producing sounds and music, and burying the deceased or commercial deals, among others. Generally speaking, portable or mobiliary artworks can be labelled as expressive objects that are differentiated from others because they are used in special settings or ceremonies and are usually restricted to specific social groups defined by gender, age, or kinship, among others. Pottery can be an appropriate example. Although plain tableware are not usually defined as artistic materials, figural and geometric paintings or carvings on ceramics transform them into artworks. More often than not, contexts uncover the special category of this kind of decorated objects.

Australian Aboriginal bark painting is also worth mentioning as an example of the complex and multiple meanings of portable art. For instance, a group of bark paintings featuring a type of Macassan boat (South Sulawesi indigenous ethnic group) used in the long journeys across Indonesia and Southern Australia has been analyzed. Besides showing the interaction between the two groups, it has been argued that these paintings embedded cultural meanings in connection to Aboriginal belief systems. In fact, painting these boats is connected to stories of creation, land, and ancestors for Aboriginal people due to the interaction with Macassan sailors (May et al. 2009).

Artworks erected or located in a fixed place can be labelled as architectural and/or monumental art. This type of art is normally related to funerary practices or to ancestor cults and other settings highly ritualized like palaces or religious and communal spaces. Furthermore, it can also present statuary, sometimes in the shape of statue-stele. Göbekli Tepe (Turkey) has provided with a striking example of such an art: dated between 9600 and 8500 BC, it is the oldest monumental/architectural artwork, so far. It consists of several circular constructions made of a combination of T-shaped stone pillars (up to 5 m height) and blocks for walls mortared with clay. Interestingly, some of pillars are carved with human and animal forms, becoming statue-stele too (Schmidt 2010). Mudbricks are a ubiquitous building material, created from a combination of clay, water, and organic cohesive elements such as straw. Walls, floors, and roofs can be recovered with plastic decoration like tiles, reliefs, engraves, sculptures, friezes, or frescoes. In many occasions, this type of art brings together locations, buildings, and people through the enactment of power and the visualization of prestige.

The last type of visual art is body art. It is normally assumed that body art is exclusively related to human bodies, but it is also possible that humans apply some kind of body decoration

to animals. A good example comes from eastern Iberia during the late Iron Age (300–200 BC), where painted pottery reveals decorated horses with necklaces holding bells and flowers on heads (Bonet and Vives-Ferrándiz 2017).

Techniques for embellishing bodies are varied and can be divided in two main types. On the one hand, body art applied on the skin like painting, tattooing, scarifying, branding, and piercing (Schildkrout 2004). On the other, artworks considered wearable art like dresses, jewels, or masks can also be categorized as body art because they are intended to be attached to the body. A major distinction concerns its permanence, as body art can be ephemeral (body and facial painting or wearable art) or durable (tattooing). In the same vein, the authorship is another relevant issue as this type of artwork includes self-ornamentation or ornamentation by others.

Body art is much more than decoration understood in terms of fashion and beauty cannons from a contemporary and western point of view. In fact, body art is inextricably related to the creation of identities. Body artworks visualize identities but also help to create social distinctions, e.g., status, gender, age, race, or kinship, among others. The displaying of designs and objects on the body is as fundamental as to being decorated. Visual information is no less relevant, as body art can be tremendously eye-catching in terms of shape, colors, or textures. For instance, during the European Bronze Age (3000–800 BC), some people were interested in sparkling artworks made of bronze. Once polished, these ornaments might have helped to define "shining bodies" and a set of social values (Harris et al. 2013: 87–94).

Art applied directly on the body, whether permanent or ephemeral, is difficult to detect because they have low archaeological visibility. Some bodies, such as those who have preserved the skin, like mummies, show traces of tattoos and scarification. For example, the Tyrolean Iceman known as Ötzi (3300–3250 BP) presents 61 tattoo marks across his body. They have been interpreted as tattoos that were part of a therapeutic treatment (Deter-Wolf et al. 2016: 21). From an anthropological-ethnographic perspective, body arts have been studied in depth (see, for instance, Alfred Gell's (1993) work on Polynesia), and it has been defined as participating in rituals of personal transformation. Texts, photographs, and interviews can also record examples of body art. On a different vein, materials that participated in the corporeal art that outlast bodies are paint residues, pigments, and painting tools. In addition the containers of these products have also been identified like small "makeup" boxes made out of fine materials like ivory or glass.

Wearable art is linked to an array of heterogeneous material culture, and one can distinguish between nonperishable materials such as metals, bone, and stone, which are recorded abundantly. At any rate, buttons, fibulae, pins, or diadems plus objects sewn onto the garments or other supports such as shells, animal bones (especially teeth), or feathers are recorded abundantly. An illustrating case study is the use of bone, teeth, and shell in Australia intended not only to decorate the body but also to participate in ritual and esoteric practices (Akerman 2018). Dresses and decorative artworks made out of perishable materials are not easily preserved, although in some special conditions, garments crafted with cotton, linen, esparto, wool, or fur are preserved due to a proper conservation atmosphere.

Finally, another indirect material to study body art is the representation of bodies whether on stone, clay, wood, etc. In many occasions these representations feature body ornamentation such as makeup, scarification, jewels, or wearable art. They might reveal corporeal art.

Performative arts provide the last type of art. This term includes music, dancing, and drama like theater or recitation as well as temporary gatherings and ceremonies that involve artworks. Unfortunately, recovering these arts from the ancient societies is an arduous task because this type of art, as it name indicates, performs some activity taking place in a specific moment and, thus, is ephemeral. However, the material culture and texts related to performances provide us with information.

Musical instruments are good pieces of evidence, from bone flutes to metallic horns. Archaeomusicology is a specific area of expertise that preserves and studies organological topics

and tries to reproduce the sounds of the past (Jiménez Pasalodos 2011). Dancing is connected to music. Here the evidence is always indirect through representations of people in certain gestures that are interpreted as dances because they follow a repetitive pattern or combine several body positions (Garfinkel 2010). Sometimes, these figures, whether isolated or in group, are accompanied by musicians.

Regarding theater or recitation, written sources are essential as they preserve some texts to sing or recite. Architectural art is also a direct evidence of performative arts as some of them were played in monumental buildings like theaters, temples, or ceremonial buildings (Inomata and Coben 2006). Direct observation, contemplation through photographs or audio and visual recordings, or participation, if possible, are good sources of information.

Other performative arts include ceremonies and gatherings like funerary rites. Ethnoarchaeological case studies have recorded artworks that were used during these enactments. For instance, bone chaplets of Arrernte, Australia, were wore by the widow and younger sisters of a dead man. These artworks were used in funerary ceremonies and once they finished the chaplets would be destroyed and dipositive in the grave (Akerman 2018: 203).

Ascenzi, Antonio

Dario Piombino-Mascali
Faculty of Medicine, Institute of Biomedical Sciences, Vilnius University, Vilnius, Lithuania
University of Messina, Messina, Italy

Basic Biographical Information

An Italian pathologist and paleoanthropologist, Antonio Ascenzi was born in Boulogne-sur-Mer, France, on May 4, 1915. He gained his medical doctor's degree from the Sapienza University of Rome in 1940. This was followed by qualification as a professor in pathology and histology in 1951 and another in anthropology in 1960. An educator at the universities of Rome and Pisa, he lectured in the fields of pathological anatomy, physical anthropology, and human paleontology (Massenti 1991). Ascenzi was appointed to the position of full professor at Rome University in the years 1968–1985. He was a member of the Superior Council for Public Education between 1966 and 1970. In addition, he accepted membership of the Commission for Auxiliary Sciences of Archaeology within the National Council for Research in 1966, of the international board for the research laboratory at the Calot Institute in 1970 and of the National Lincean Academy in 1987 (Massenti 1991; Giuffra et al. 2010). In 1973, he was appointed president of the Italian

Institute of Human Paleontology, a post that he held for the rest of his life. During his career, Antonio Ascenzi received a number of important awards, including a gold medal for merits in the fields of education, culture, and art in 1984 (Massenti 1991; Ascenzi 2001). He died in his home at Albano Laziale on December 18, 2000.

Major Accomplishments

Over the last century, Antonio Ascenzi has been one of the most prominent figures of Italian biological anthropology. He greatly contributed to the study of archaeological human remains by applying a wide range of scientific methods to their analyses, including light microscopy, electron microscopy, histology, histochemistry, and radiology (Giuffra et al. 2010). Among his paleoanthropological achievements, we can include the finding of an incomplete Neanderthal mandible in 1950 at Guattari cave and the study of additional hominid remains from Saccopastore, the Circeo cape, and Archi. In addition, he researched the traits of the noted Ceprano calvaria, currently considered an early stock of *Homo heidelbergensis*. This important specimen also revealed the presence of healed trauma and of a congenital malformation of the sphenoid sinus (Giuffra et al. 2010). Fascinated by paleopathology, the scientist contributed to the diffusion of this discipline in Italy and focused on the diagnosis of thalassemia in skeletal remains (Giuffra et al. 2010). Antonio Ascenzi was also interested in bone alterations and taphonomy and carried out experimental archaeology in order to shed light on postdepositional processes on the bone buried in the dirt or immersed in water (Giuffra et al. 2010). Last but not least, he was interested in mummified remains and headed investigations of the Uan Muhuggiag infant mummy from Libya, as well as those of the famous Grottarossa mummy, a rare example of Roman mummification (Aufderheide 2003). In this specific study, analyses revealed the presence of lines of arrested growth, osteopenia, anthracosis, and pleurisy, all of which are of paleopathological relevance (Cockburn et al. 1998). For all of these significant contributions, Ascenzi is considered the "father" of modern paleopathology and mummy studies in Italy (Fornaciari 2013).

Ash: Geoarchaeology

Matthew Canti
Historic England, Fort Cumberland, Eastney, UK

Introduction

Ash plays a significant role in archaeology both as a building block of stratigraphic accumulation and as an alkaline source in taphonomic pathways. It

is found all over the world and can be of considerable value in understanding cultural activity. Ash is a major component of many cave stratigraphies (e.g., Brochier 1983; Berna et al. 2012; Shahack-Gross and Ayalon 2012), where leaching is minimal and occupation or animal stabling has occurred regularly throughout history. Ash also occurs at open-air sites under arid climatic regimes (Cremaschi and Trombino 1999), in pit fills where the shape and bulk of the deposit discourage dissolution, and in layers where the surrounding sediments are sufficiently alkaline (e.g., Canti 2007).

Definition

The word "ash" covers the remains of any burnt material and appears commonly in nineteenth- and early twentieth-century chemical analysis meaning "the component that cannot be oxidized." In practical parlance, however, it refers to the material left over from solid fuel fires. Archaeological ash can occasionally be the result of coal burning, particularly with the growth of industrial archaeology; however, in most cases, ash found in excavations results from the burning either of plant material or dung derived from herbivores. This entry will deal only with ash from plants and dung.

Historical Background

Although ash was reported from excavations throughout the twentieth century, it has only been studied analytically during the last 50 years or so. As with other aspects of archaeological science, early analytical studies did not approach the subject systematically, so an understanding was only built up slowly from individual pieces of work, such as the elemental analyses of ash mounds in central southern India (Zeuner 1959).

Folk (1973) was the first to indicate the true botanical origin of the calcium carbonate which forms a large part of many ash bodies, but this material and its relationship to the more siliceous ashes derived from grasses and herbivore dung (see below) were not fully understood until the work of Brochier (1983, 1996) and Brochier et al. (1992).

Subsequently, the major focus for published work on ash has been the diagenetic pathways in the Mediterranean and Middle Eastern caves. In these environments, ash, guano, and bone provide uniquely reactive contextual chemistry involving transformation pathways of numerous different phosphatic minerals, which enable valuable interpretations to be made both of the original inputs and the preservation of the environmental remains (Karkanas et al. 2000; Stiner et al. 2001).

Key Issues and Current Debates

What Is Ash?

Various parts of plants have been burnt throughout history by all cultures to produce heat. The materials used can range from fine grasses to woody stems with leaves or logs from large trees. All these plant products are predominantly made of carbon-rich compound such as cellulose and lignin which burn away. However, they also contain a significant mix of mineral components that are left behind (either intact or modified) to become the ash layers found in archaeological excavations. The major mineral components are calcium carbonate (derived by burning from calcium oxalate crystals in the original plant) and silica which mostly comes through unchanged from phytoliths in or around plant cells.

The calcium oxalate crystals come in two major forms, both of which are preserved in the final ash body. The first of these is prismatic crystals, which form various rhomboidal shapes and commonly line the veins in leaves of numerous plant species (Fig. 1). The second is druses, which are aggregates of radially deployed crystals typically found lining veins or in the parenchymatous tissue (Fig. 2).

The shapes of the opaline silica remains are highly variable. Some form discrete bodies known as phytoliths, while others result from encrustation of the cells and retain a cellular shape after the organic remains have burned away (Fig. 3).

Ash: Geoarchaeology, Fig. 1 (**a**) Prismatic calcium oxalate crystal from *Laurus nobilis* (SEM photo), (**b**) prismatic crystals in leaf veins of *Quercus robur* (bleached whole leaf in crossed polarized light), (**c**) prismatic crystals converted to calcium carbonate in modern bonfire ash from mixed sources (plane polarized light)

These compounds represent two major trends in plant mineralization. Some form of silica is present in most plant species but especially rich in the grasses; calcium oxalate is widespread in herbaceous plants and trees but is absent from the grasses. There are other mineral components in ash, and there are further complexities in the physiological and botanical relationships. A more complete discussion can be found in Canti (2003).

An additional modified form of ash occurs when some of these components become fused together. This happens when the ash contains a significant proportion of fluxing agents such as sodium and potassium which lower the melting point when mixed with silica (Robinson and Straker 1991). The results can vary from delicate crisp frameworks of the original plant silica through to lumps of glassy clinker-like material, sometimes vesicular (Fig. 4) due to gas bubbles developing in a liquid melt (Folk and Hoops 1982; Canti 2007).

Once ash has been fully mineralized, the resulting chemical mix has considerable value to people without access to modern chemicals. Careful species selection can make for worthwhile differences in the salts obtainable from ash – a fact still exploited by non-Western peoples today (see Lemonnier 1984). The chemical makeup is variable but is frequently of such a composition that it can be used to glaze ceramics, usually with small additions of clays or other oxides (Rogers 1991). A long tradition of ash glazing built up in Asia over the last 1,000 years, producing some of

Ash: Geoarchaeology, Fig. 2 (**a**) Druse crystal from *Rheum raponticum* burnt at 700 °C (SEM photo), (**b**) druse calcium oxalate crystals from *Rheum raponticum* (crossed polarized light), (**c**) druse crystals converted to calcium carbonate in modern bonfire ash from mixed sources (plane polarized light)

the most exquisite ceramics (see Leach 1940). The melting characteristics of ash also made it one of the first major ingredients used in glass manufacturing (Turner 1956).

The predominant geographical location of ash research has been cave studies in calcareous Mediterranean rocks. In conjunction with the use of polarized light microscopy as a major analytical method, this has led to a particular emphasis being placed upon distinguishing geological and pyrogenic calcium carbonate. The stratigraphy in these locations commonly contains both forms of calcium carbonate, and they are often difficult to tell apart under the microscope. Although the modified calcium oxalate crystals are easy to recognize intact, they can disintegrate or become compressed and sometimes recrystallized in such a way as to obscure the differences in origin.

Two approaches have been employed to try and achieve the desired distinction. Firstly, comparison of the different calcite peaks produced by infrared analysis can distinguish the main forms of calcite in sediments where recrystallization has not occurred (Regev et al. 2010). Secondly, examination of C and O isotopes distinguishes the sources because of the differences in the original isotopic composition of the plant matter, air, and limestone which form the inputs.

As well as successfully separating the ash from the rock, the isotopic approach has raised further

Ash: Geoarchaeology, Fig. 3 Silica remains of burnt *Equisetum* sp. (plane polarized light)

Ash: Geoarchaeology, Fig. 4 Vesicular ash melt from excavations in Woolmonger St., Northampton, UK (plane polarized light)

questions by showing that the ash itself has different isotopic compositions (Shahack-Gross et al. 2008). These differences arise primarily from the fact that there are two distinct pathways to the formation of calcium carbonate from calcium oxalate. The first is a low-temperature (400–500 °C) transformation in which $CaCO_3$ forms directly by loss of CO, i.e., simply redeploying the carbon already in the crystal (Dollimore 1987; Frost and Weier 2003, 2004). The carbon in the plant oxalate will be isotopically consistent with the fuel plant's photosynthetic pathway and will thus tend to fall into one of the well-known C3- or C4-type plant carbon groupings.

The second is the high-temperature transformation which goes through modification stages similar to traditional lime burning for mortar and plaster. At around 600–700 °C, carbon dioxide (CO_2) is given off leaving quicklime (CaO) which then hydrates to form calcium hydroxide $Ca(OH)_2$. Over time, this hydroxide absorbs atmospheric CO_2 to reform calcium carbonate ($CaCO_3$) again. A combination of these two pathways inevitably occurs in real fires, and the isotopic compositions of archaeological ash can thus be shown to reflect mixing lines involving the original plant matter, as well as atmospheric and geological inputs (Shahack-Gross and Ayalon 2012).

Folk (1973) pointed out the potential value of calcitic ash for radiocarbon dating based on the chemistry of this high-temperature transformation in which the carbonate from atmospheric sources would have a radiocarbon date the same as the atmosphere at the time of the fire. However, he did not allow for the low-temperature form of transformation in which calcium oxalate changes to calcium carbonate without atmospheric inputs. This type of transformation would lead to a radiocarbon date similar to the carbon in the original oxalate crystals and thus be analogous to the "old wood effect" where charcoal used for dating a layer is found to be older than the formation of that layer.

In an effort to clarify the potential of plant ash for radiocarbon dating, Regev et al. (2011) burnt different plant materials of known radiocarbon characteristics at different temperatures and compared the results from the ash with the results from the original material. They found that, when burnt at low temperature (500 °C), the ash largely retained the original calcium oxalate radiocarbon concentration but with a slight shift toward atmospheric concentrations. As would be expected, all the material burnt at high temperature (900 °C) showed complete CO_2 exchange with the atmosphere. The mechanism for the low-temperature shift remains unknown.

International Perspectives

The high percentage of calcium carbonate that characterizes most ash means that its archaeological occurrence at outdoor sites is inevitably negatively correlated with rainfall and, apart from the wet tropics, tends toward a similar relationship with latitude as well. In more northerly climates, the calcareous component of ash is commonly leached away, and only the charcoal is left behind, attesting to its former presence. Sites on calcareous geology will retain ash where it gets sufficiently buried to be protected against leaching. These cases are sometimes deep pit fill deposits associated with domestic waste disposal or industrial installations such as the corn drying ovens at Grateley, Hants, UK (Cunliffe and Poole 2008). Rare occurrences are sometimes found elsewhere, if enough alkaline material is present. At Flixborough, Humberside, UK, blown siliceous sand with only a minor calcareous component was deep enough to preserve ash in significant quantities, influencing the taphonomy at the site and retaining Anglo-Saxon bone layers in very good condition (Canti 2007).

Further south, ash deposits are more commonly found, and the analytical value can be high in situations where the burning of plant matter is accompanied by other lines of evidence. In particular, information from the more detailed botanical attribution of plant silica remains, and the concentrations of fecal spherulites (calcium carbonate remains from dung) can together stimulate deductions about industrial or agricultural activity. The Numidian layers at Althiburos in northern Tunisia, for example, were composed of ashy sediments that provided excavators with insights into the detail of animal keeping and domestic life (Portillo and Albert 2011). Concentrations of inflorescence or whole plant phytoliths, in association with fecal spherulites, provided information on feeding style and seasonality, while spherulites in oven ash showed the use of dung as fuel. At Atar Haroa, an Iron Age site in the Negev Highlands of Israel, Shahack-Gross and Finkelstein (2008) were similarly able to distinguish indoor ash deposits derived through dung and wood burning from external dung-only deposits by utilizing phytoliths and spherulite analysis.

Dung burning appears to be the central reason for the huge ash spreads that occur in parts

of central Africa and southern India. These are mounds many meters high in some cases or covering hundreds of square meters in others. They contain elements of ordinary soil, ash, and fused ash – the latter being the reason for much analytical discussion (Zeuner 1959; Allchin 1963; Thy et al. 1995). Cattle dung was piled up at various times in history and prehistory and then deliberately or accidentally burned producing enough heat to cause fusion (see above).

Future Directions

If the shift toward atmospheric carbon shown by Regev et al. (2011) could be understood, it might open the way to using ash for radiocarbon dating. In practical application, there would still be the problem of diagenetic alteration, as ash in the presence of water can undergo calcium carbonate precipitation at any time between deposition and excavation, and that would be likely to introduce carbon from other sources. However, it could be possible to overcome this through careful sample selection, perhaps using microscopy or isotopic separation.

The greater detail recently made possible in the isotopic distinctions of ash types and their formation pathways clearly gives a new direction in the study of this remarkable material. As ever with archaeological science, the challenge remains in taking the laboratory understanding out to the field and using it to produce real interpretations among the indistinct or mixed contexts of real-life archaeological sites.

Ashby, Thomas

Richard Hodges
American University of Rome, Rome, Italy

Basic Biographical Information

Thomas Ashby (1874–1931) was an archaeologist who specialized in the study of the topography of ancient Rome and its hinterland, the campagna romana. Born on October 14, 1874, he was the only child of Thomas and Rose Ashby, Quakers who owned a brewery in Staines, Middlesex. After Winchester College, Ashby won a scholarship to Christ Church, Oxford, studying ancient history, classics, and archaeology with Francis John Haverfield and J.L. Myres. He pursued a doctorate on Roman antiquities, exploring the hinterland of Rome in the company of the British and American Archaeological Society of Rome which included his father as well as the distinguished Italian archaeologist, Rodolfo Lanciani (1845–1929). He died while on a visit to London on May 15, 1931.

Major Accomplishments

In 1902, he became the first student of the British School at Rome, continuing this institutional association when he became the school's assistant

director (1903–1906) and then its third and most distinguished director from 1906 to 1925. During his directorship, with Eugénie Strong as his assistant director from 1909 to 1925, he established the school as an academic force in Italy, overseeing the move to the present location in the Valle Giulia and winning critical operational support from the British government's newly founded British Academy in 1919. In 1924, the school's executive committee decided not to renew either Ashby or Strong after 1925 to the dismay of the academic community in Rome. Thereafter, Ashby, who had married May Price-Williams in 1922, moved to a small apartment in Rome, where he lived until his death in 1931.

Ashby was primarily a topographer of Rome and its hinterland during the Roman period. As an avid photographer and walker, he followed the Roman roads and aqueducts out of the ancient metropolis, mapping them as he did. He was also a serious bibliophile, assembling a significant library of post-Renaissance books about Rome and its hinterland. The most important of a prodigious number of publications included many essays and reports on the monuments in the campagna romana, which later formed the nucleus of his popular book, *The Roman Campagna in Classical Times* (Ashby 1927), and his encyclopedic, posthumous masterpiece, *The Aqueducts of Ancient Rome* (Ashby 1935). He also published important studies of metropolitan Rome such as a revision of Samuel B. Platner's *A Topographical Dictionary of Rome* (Platner and Ashby 1929) and *Turner's Visions of Rome* (Ashby 1925).

Ashby's interests were not confined to antiquity. This energetic scholar also studied Sardinian nuraghi and the prehistoric megalithic tombs of Malta and Gozo and wrote an ethnographic study on Italian life and folklore: *Some Italian Scenes and Festivals* (Ashby 1929). His collection of photographs, besides his archive of notes, remains an important source for the study of Italy before mechanized agriculture and of Rome as it was being made into a capital city. Deeply respected by his Italian contemporaries, this shy and serious scholar established a benchmark for topographic fieldwork in Italy that was not surpassed until the 1960s.

Ashmore, Wendy

Cynthia Robin
Department of Anthropology, Northwestern University, Evanston, IL, USA

Basic Biographical Information

Archaeologist, anthropologist, and mentor, Wendy Ashmore was born on June 26, 1948 in Los Angeles, California. In the 1950s, at the height of McCarthyism, her family moved to Mexico City for a year. The experience fueled her interest in Mesoamerican studies. Educated at the University of California, Los Angeles (B.A. in Anthropology, 1969), and University of Pennsylvania (Ph.D. in Anthropology, 1981), she taught at Rutgers (1981–1992) and the University of Pennsylvania (1992–2000) before joining the

Ashmore, Wendy, Fig. 1 Wendy Ashmore. (Photo by Amy Goldenberg)

faculty at the University of California, Riverside. She has carried out archaeological investigations of ancient Maya and neighboring Mesoamerican peoples in Guatemala (Quiriguá), Honduras (Gualjoquito, Copan), and Belize (Xunantunich). Notable in its appreciation for the significance of empirical data and their relationship with theory and practice, Ashmore's research led successively over the years to new ways of thinking about settlement patterns, the significance of households, civic planning, and their linkages with landscapes, cosmology, and gender. Paramount across all of these is the social use and understanding of space. By exposing the social contours of archaeological spaces, Ashmore's work led the way for nuanced studies of the diverse peoples that make up any past society (Fig. 1).

Major Accomplishments

Ashmore's initial research at Quiriguá (1975–1979) and Gualjoquito (1983–1986), the later codirected with Edward Schortman and Patricia Urban, were among the first studies of prehistoric settlements and households. Examining a 96 km^2 area adjoining and in the periphery of the Maya center of Quiriguá, Ashmore (1979, 2007) identified the varied lives of Quiriguá residents and how these resonated with broader social and political dynamics.

Ashmore's pioneering research in settlement and household archaeology in the 1970s and 1980s helped elevate these studies to their now central position in archaeology. In two seminal volumes, *Lowland Maya Settlement Patterns* (1981) and *Household and Community in the Mesoamerican Past* (1988, coedited with Richard Wilk), she and her colleagues synthesized past research, defined relevant social constructs and their archaeological correlates, and suggested fruitful avenues for future scholarship. These volumes remain defining statements; they set the stage for the post-1980s explosion of settlement and household studies in Mesoamerica and beyond that allowed archaeologists to expose the lives of the full range of people in ancient societies.

Archaeological theory in the 1990s was framed by a strong dichotomy. In broad brushstrokes, American processual archaeology, espousing a scientific epistemology grounded in cultural materialism, neoevolutionism, and cultural ecology, was contrasted with European postprocessual archaeology, which favored historical explanations, employing hermeneutic and critical epistemologies to understand symbolic and ideological aspects of past societies. Ashmore's research played an important role in bridging these two poles. By critically thinking through the concept of social process – a concept with roots in processual archaeology – Ashmore was able to show how the archaeological record was simultaneously material and conceptual and part of an ongoing construction of its inhabitants in a manner that was convincing to processualists and postprocessualists.

Ashmore's Copan North Group Project (1988–1989) was pivotal in crystallizing such an approach. Through detailed excavation and analysis of architecture, iconography, artifacts, and burials at Copan's North Group, she demonstrated

that the Classic Maya expressed ideational beliefs through material and spatial forms that were accessible to archaeologists. In her groundbreaking article "Site Planning Principles and Concepts of Directionality among the Ancient Maya" (1991) and in many subsequent articles and book chapters in English and Spanish, Ashmore's work in spatial archaeology has shown that how people organize and conceptualize space, shapes and is shaped by society and social action (e.g., Ashmore 1998; Ashmore and Sabloff 2002).

This larger project led to another field defining work: *Archaeologies of Landscape* (1999, coedited with Bernard Knapp), a volume in which themes that Ashmore previously developed within Mesoamerican archaeology were applied to studies from around the world. Later, Ashmore (2006) brought landscape archaeology into productive concert with gender studies by illustrating how gender and landscapes can be co-constituting.

Bringing together previous interests, as the Archaeology Division of the American Anthropological Association's Distinguished Lecturer in 2000, she developed an approach to socializing the spaces of the archaeological record demonstrating how spaces, places, and landscapes are cultural domains that are lived and experienced differently by people across their lives. This lecture "'Decisions and Dispositions': Socializing Spatial Archaeology" later published in *American Anthropologist* (2002) illustrated that by socializing spatial analysis, archaeologists could reveal people's materialized "decisions and dispositions" throughout the life histories of the places they study.

Her long-standing interest in invigorating, rather than silencing, the varied voices in archaeological thought came together in an edited volume *Voices in American Archaeology* (2010, coedited with Dorothy Lippert and Barbara Mills). This volume brought into dialogue diverse voices of the discipline to consider the political and professional implications of archaeology and its future.

For Ashmore, research and scholarship always entailed pedagogy and mentorship. Prominently seen in the Xunantunich Archaeological Project (1991–1997), codirected with Richard Leventhal, she developed research as a vehicle for her students. Through regional settlement, household, and community survey and excavation in the environs of the polity capital of Xunantunich, Ashmore and her students explored the social, political, and ideational underpinnings of life in the region as Xunantunich rose and fell (e.g., Ashmore 2010).

Respected as a teacher and colleague, Ashmore has received numerous teaching and service awards. Her role as a mentor extends beyond her students and colleagues to a broader arena through two textbooks – *Discovering our Past* and *Archaeology* – used in classrooms national and internationally (Sharer and Ashmore 2003; Ashmore and Sharer 2010). The former has been translated into Chinese and Polish.

Since the 1970s, Ashmore has employed theoretically sophisticated methodologies and problem formulations to provide increasingly textured interpretations and understandings of the evidence, the society, and even the methodology itself. Throughout her career, she has defined significant new fields of archaeology from settlement and household to landscape studies and reformulated fieldwork to expose the peripheries of sites and explore ideational domains. These contributions have been accompanied by increasingly nuanced interpretations and understandings of the diverse and changing social structures of Mesoamerican societies. Her work influenced even her critics due to its considerable attention to empirical evidence.

Asian Paleolithic Association (APA)

Ying Guan
Department of Paleoenvironmental Study, Institute of Vertebrate Palaeontology and Palaeoanthropology, Beijing, China

Basic Information

The Asian Paleolithic Association (APA) is an international organization which aims at promoting and enhancing the academic communication of Paleolithic Archaeological and Paleoanthropological research in Asia. In 2007, an agreement was made by the representatives from Russia, China, Japan, and Korea, which addressed the establishment of an association on Paleolithic research in Asia and the adjacent area. The title *Asian Paleolithic Association* was for the first time proposed in this agreement. In June of 2008, during the *International Symposium Commemorating the Centennial Anniversary of Academician A.P. Okladnikov – The Current Issues of Paleolithic Studies in Asia and Contiguous Regions*, held in Novosibirsk of Russia, scholars from Russia, China, Japan, Korea, North America, and European countries reached an agreement of officially setting up this organization. This meeting was thus proposed as the inaugural conference and the first annual meeting of APA.

Each member country of the APA, referring to Russia, China, Japan, and Korea, keeps an independent, equal, and reciprocal relationship. The annual meeting is held in these four countries, in turn, each year or 2 years. There is no independent secretariat system; however, each country will serve two representatives who would be in charge of the task force for the preparation process for the annual meeting.

In October 19–23, 2009, the second annual meeting *International Symposium on Paleoanthropology in Commemoration of the 80th Anniversary of the Discovery of the First Skull of*

Peking Man was held in Beijing, China. In October 10–15, 2010, the third annual meeting was held in Gongju, Korea. In November 25–30, 2011, the fourth annual meeting *Symposium on the Emergence and Diversity of Modern Human Behavior in Palaeolithic Asia* was held in Tokyo, Japan. And in 2012, the fifth annual meeting was held in Russia.

In June 26–30, 2013, the sixth annual meeting was held in Yinchuan, China, and in November 12–14, 2014, the seventh annual meeting was held in Kongju, South Korea. In June 24–28, 2016, the eighth annual meeting was held in Tokyo, Japan.

Major Impact

This organization is young but flourishing. Since its naissance, the research and the academic communication of Paleolithic archaeology in Asia has been strongly activated. During the past four annual meetings, representatives have presented various topics including the origin of early *Homo*, the origin of modern humans, the migration of early *Homo* and early modern humans, and the varieties and communication of different Paleolithic complexes, lithic analyses, taphonomy and zooarchaeology in prehistoric contexts, paleoanthropology, paleoenvironmental archaeology, and so forth. More technologies and scientific methods have been applied in these fields and brought more clues and evidence for archaeology in Asia. APA would behave as the driving and cohesive force and continue to promote and enhance these research fields in the future.

Askarov, Akhmadali A.

Nona A. Avanesova[1] and Vladimir I. Ionesov[2]
[1]Department of Archaeology, Samarkand State University, Samarkand, Uzbekistan
[2]Department of Theory and History of Culture, Samara State Academy of Culture and Arts, Samara, Russia

Basic Biographical Information

Askarov Akhmadali Askarovich (born in 1935) (Fig. 1) is an academic with the Academy of Science of Uzbekistan, a doctor of historical sciences, and a professor in ancient history of Central Asia. He is an organizer of archaeological science in Uzbekistan.

After graduating from the historical faculty at the State Pedagogical Institute in Tashkent in 1957, A.A. Askarov worked as a teacher in the middle school. From 1958 to 1961, he studied at the postgraduate school in Leningrad's Department of the Institute of Archaeology, under the scientific

Askarov, Akhmadali A., Fig. 1 A.A. Askarov

supervisor of Professor M.P. Gryaznov. In 1963 he defended a thesis on the theme "Lower Reaches of Zeravshan River in Bronze Age." In 1977 he was awarded the degree of doctor of historical sciences for the thesis "Bronze Age of Southern Uzbekistan: to the Problem of Development of Local Centres of Ancient-Eastern Civilizations."

A.A. Askarov has been a scientific fellow since 1961. Since 1966 he has been deputy of director of Institute of History and Archaeology of Uzbekistan USSR and since 1970 director of the Institute of Archaeology of Uzbekistan.

Major Accomplishments

The scientific interests of A.A. Askarov have focused on prehistorical archaeology – the histories of ancient tribes of Bronze and Early Iron times. Askarov has participated actively in works of significant large expeditions (Baikal, Krasnoyarsk, Makhandarian, Sud-Turkmenistan), led by such famous Russian scientists as M.P. Gryaznov, Y.G. Gulyamov, and V.M. Masson. A.A. Askarov has led the Surkhandarya Complex Expedition since 1970.

A.A. Askarov has made an enormous contribution to research into the history and spiritual culture of the ancient steppe tribes of Southern Asia. He has elaborated an archaeological periodization for development of the steppe tribes's cultures of Bronze and Early Iron times for Lower Reaches of Zeravshan River. In addition, he has reconstructed the whole history of tribes and settlements for this region in the second millennium BCE.

A.A. Askarov has been conducting significant researches in Uzbekistan for about 40 years. His achievements are well recognized in the study of proto-urban civilization, the genesis of urbanization, the transformation of primitive-communal cultures, and the formation of an early-class society through the archaeological materials. He has prepared and published more than 300 works, including 12 monographs and 2 tutorial books. A number of these works were published abroad. One of the monographs is dedicated to the ancient agricultural civilization of Southern Uzbekistan "Kuchuk-Tepe" and was presented to the world by the publishing house of Institute of Archaeology in Berlin. Askarov is one of the authors of the six-volume *History of Civilization of Central Asia*, produced by UNESCO. Under his editing, 13 volumes of the series *History of Material Culture of Uzbekistan*, 10 monographs, and numerous of booklets in Uzbek language were published.

For many years, A.A. Askarov conducted stationary excavations and planigraphical investigations of monuments of antiquity in Uzbekistan. Thanks to his field studies and discoveries, the existence of an earlier unknown South Uzbekistan center of Ancient Bactrian Civilization was proved. The Ancient Bactrian Centre was uncovered and comprehensively characterized by Askarov. Based on his scrutiny of the Sapalli Culture sites (Sapallitepa and Djarkutan sites), he defined a historical place of these objects in the cultural system of Ancient East and in wide context of intercultural relations of neighboring cultures and civilizations.

Askarov's unique discoveries have important historical meaning, including him finding of silk, bast, and cotton tissues in burials of Sepallitepa. This contributed to proving that the production of natural cotton and silk in Uzbekistan was started in the Bronze Age. He was one of the first who raised the question that the territory of Uzbekistan may have been one of the homelands of silk weaving and cotton weaving.

Askarov's discovery of the cult center – the Temple of Fire in Djarkutan – provided important evidence on the genesis of a Zoroastrian ideology during the late Bronze Age. Research into this unique complex provided an opportunity to track sources of Zoroastrian doctrine and to obtain new dates (second half of second millennium BCE) for the appearance of the cult of fire in the history of Zoroastrianism.

The history of irrigated agriculture in Uzbekistan has become more ancient by a thousand years due to the rich archaeological material uncovered in long-term field investigations by A.A. Askarov. The great merit of Askarov's investigations lies with his research into the culture of late molding painted pottery. His study demonstrated that the carriers of this tradition were local tribes of the

end of the second and beginning of the first millennium BCE. These tribes were transitioning to agriculture under the influence of more developed ancient urbanistic and agricultural communities of the south.

The numerous archaeological discoveries were done thanks to Askarov; his publications have been recognized with world scientific community as significant contributions in study of early history of Central Asian Civilizations. The results of these researches are widely used not only as theoretical works but have entered into the scientific and pedagogical programs of universities.

Askarov also suggested a new conception of the ethnogenesis of the Uzbek people, according to which the historical formation of the Uzbek people as a people took place on the basis of centuries-old, mutual ethnic assimilation of the indigenous Turkic, Sogdian, Khorezm, and Bactrian tribes and peoples of Central Asia in the territory of modern Uzbekistan and its environs.

Assemblage Thinking

Kelly D. Wiltshire
Department of Archaeology, College of Humanities Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Assemblage thinking is a concept that originally derived from the work of French philosophers Giles Deleuze and Félix Guattari in their book *A Thousand Plateaus: Capitalism and Schizophrenia* (1980). This concept has been further developed and applied within the fields of social sciences by Bruno Latour and political sciences by Manuel DeLanda; however, these applications depart from Deleuze and Guttari's original concept, which derives from the French word "agencement" – a noun that means an arrangement or layout and has greater semantic depth than the English term "assemblage." Despite this, the application of assemblage thinking within the archaeological discipline has drawn upon a mixture of Latour's and DeLanda's rendering of the concept, which has been applied to form the field of symmetrical archaeology.

Definition

Assemblage thinking provides a means to describe and understand the relationship between the heterogeneous actors that form particular social assemblages or societies. Heterogeneous actors comprise "(all) those enormously varied physical entities we refer to as 'material culture', [and] are beings in the world alongside other beings such as humans, plants, and animals" (Olsen 2012: 212). Actors include texts, equipment, practices, and organizations, as well as less tangible entities such as decisions, ideas, concepts, and metaphors (Harman 2007: 36; Olsen 2007: 582). Therefore,

> everything that exists must be regarded as an [actor]. . .We cannot begin by splitting actants into zones of animate and inanimate, human and non-human, or subject and object. Every entity is something in its own right, and every entity becomes involved in associations, love affairs, and duels with many others (Harman 2007: 36).

In Latour's (2005) manifesto, *Reassembling the Social: An Introduction to Actor-Network Theory*, assemblage is used as a metaphor to understand agency between heterogeneous actors that comprise social assemblages (or networks). For Latour (2005) the agency of actors is possessed in connections between actors rather than in actors themselves, with agency relative to and distributed via the assemblage or network within which they are situated. Therefore, actors work together to form an assemblage and exercise agency via said assemblage; without the assemblage, an actor has no agency (Harman 2007: 43).

On the other hand, DeLanda's (2006) social philosophy, *A New Philosophy of Society: Assemblage Theory and Social Complexity*, posits the heterogeneous actors that comprise social assemblages both have material and expressive intrinsic qualities independent of their relationship with other actors. For DeLanda (2006: 18–19), an actor has the ability to influence, stabilize or destabilize particular assemblages, regardless of whether such actors are connected to or remain outside a given assemblage.

While Latour (2005) and many of his of Science and Technology Studies (STS) contemporaries have drawn upon assemblage thinking in the development of Actor-Network Theory (ANT) to study the sociology of scientific knowledge production, DeLanda (2006) has applied assemblage thinking in order to provide an alternative account for the historical formation of institutions, governments, cities, nations, modes of production, and capitalism.

Key Issues/Current Debates/Future Directions/Examples

While the term assemblage has a long history of use in archaeology as a classificatory term to describe a group of artifacts, the renewed interest in assemblage as a metaphor within the archaeological discipline is influenced by the recent "material turn" within the social sciences and humanities; however, Hamilakis and Jones (2017: 80) argue: ". . .our growing fascination with the concept has to do, to a large extent, with our familiarity with archaeological assemblages, with the primacy that this word holds on our collective disciplinary imagination."

The development of symmetrical archaeology has been a pivotal field in this renewed interest. Symmetrical archaeology seeks to apply the ANT concept of *symmetry* in order to draw attention to the often marginalized or silenced agency of non-humans, which has been concealed by the creation of modern thought that emerged during the Enlightment. During this period French philosopher René Descartes asserted the human mind was active and separate from all other non-human matter, promoting an anthropocentric understanding of our modern existence that resulted in a dichotomy or disentanglement between humans and nonhumans. This anthropocentric understanding resulted in the assumption that the primacy of agency rests with humans, with nonhumans misrepresented "(as) inert, stable, and ultimately entirely vulnerable to human action and conception" (Knappet 2012: 194).

In contrast, the premise of symmetrical archaeology considers the status and agency of humans and nonhumans as symmetrical. Under a

symmetrical rhetoric, nonhumans are not passive, inert, or inanimate but are actors with the capacity to act alongside human actors. Thus, the concept of symmetry seeks to promote the equal agency of human and nonhuman actors in order to create a "flat ontology," which treats all human and nonhuman democratically and moves away from an anthropocentric view of agency.

In applying this concept, symmetrical archaeology argues the archaeological discipline produces anthropocentric histories that emphasize the "Indian [sic] behind the artefact" (Braidwood 1958: 734), but have failed to recognize the agency of nonhumans or things. In essence, things have been forgotten. For example, key practitioner of symmetrical archaeology Bjørnar Olsen (2007: 580, 582) believes the archaeological discipline and the histories it produces have kept things at arm's length:

> (what) we see is basically a prolonged asymmetry, in which things continue to be treated as secondary or epiphenomenal to some cultural or social 'first instance'. . .[where] the material inhabitants were plastic and receptive, sitting in silence waiting to be embodied with cultural significance.

Alternatively, symmetrical archaeology can offer a distinct and reconceptualized focus on things, where the metaphor of an assemblage is used to better understand the agency of things. For example, things make a difference, not just because of their agency and ability act, but because of the mutually constitutive connection that exists between human and nonhuman actors as part of an assemblage or network (Latour 2005). A symmetrical approach seeks to consider the connections or entanglements that exist between humans and nonhumans that have been misrepresented and oversimplified by modern thought. In doing so, proponents of symmetrical archaeology argue being sensitive to these entanglements can result in far more complex archaeological interpretations (Olsen et al. 2012: 14).

While this emphasis on agency existing in the connections between humans and nonhumans draws upon the Latourian strand of assemblage thinking, Olsen (2012: 219) maintains nonhumans have a distinct "thingness" or "thingly quality" that also aligns symmetrical archaeology with DeLanda's rendering of this thinking. In applying these renderings, the key criticisms of symmetrical archaeology – which are also the key criticisms of ANT – relate to its emphasis on the equal agency of human and nonhuman actors and its "flat ontology." Critics claim this democratic approach does not account for or challenge preexisting systems of asymmetrical power and authority or inequality (Amsterdamska 1990; Restivo 2005; Whittle and Spicer 2008). Despite this, ANT understands hegemonic systems of power and authority as a product or effect of preexisting assemblages; assemblages that ANT seeks to describe and understand (Latour 2005: 64).

Building upon the development of symmetrical archaeology, Ian Hodder's (2012) *Entangled: An Archaeology of the Relationships Between Humans and Things* also draws upon the assemblage metaphor to explore the spatial and temporal relationships between humans and nonhumans. In doing so, Hodder (2012: 91–94) initially explores the concept of ANT but soon rejects it on the basis of its symmetry and instead favors the concept of entanglement to convey the dependence that exists between human and nonhumans; in essence, humans and nonhumans are dependent on and affect each other as a result of their entanglement. Drawing on DeLanda's rendering of assemblage thinking, Hodder (2012: 95) also emphasizes the contingent material properties of nonhumans, which not only contribute to their entanglement with humans but also allows for their archaeological study through time. In doing so, Hodder uses examples from his long-term research at Çatalhöyük in Turkey in order to demonstrate such entanglement. Employing the use of a "tanglegram," Hodder (2012: 67) demonstrates how the use of clay as a physical property to produce house bricks resulted in environmental change that in-turn produced change in subsistence behaviors. As a result of their dependence on clay, the population at Çatalhöyük became entrapped into an entangled relationship with this resource that produced new entanglements with their environment. In short, Hodder (2012: 171) argues human populations are destined to depend further on non-humans, becoming entrapped into an irreversible, evolving

relationship of progression that leads to increased entanglement over time.

Taking the application of assemblage thinking one step further, Rodney Harrison (2011) provides a philosophical discussion to address a different dichtomy that emerged as a result of the Enlightment: the dichtomy between past and present. This dichtomy – which is also discussed at length by practitioners of symmetrical archaeology (see Olsen 2012; Olsen et al. 2012) – promotes a metaphorical understanding of archaeology-as-excavation, whereby archaeology is seen as a practice that discovers a hidden or buried past separate from the present. Harrison (2011: 155–157), however, argues this modernist conception of archaeology-as-excavation should be replaced with an alternative metaphor of archaeology-as-surface-survey, whereby the past and present exist on the same temporal plane or surface. In utilizing this metaphor, archaeological practice can be reconceptualized as a process of "assembling/reassembling" the past and present, where the past is an actor with agency in present that intervenes and forms part of the assemblage that comprises contemporary archaeological practice; or as Harrison (2011) describes it, an archaeology *in* and *of* the present.

More recently, Harrison (2015) has applied this philosophy more thoroughly to reconceptualize heritage as a concept that emerges from a process of assembling the past, present, and future, stating that:

> While heritage is produced as part of a conversation about what is valuable from the past, it can only ever be assembled in the present, in a state of looking toward, and an act of taking responsibility for, the future (Harrison 2015: 35).

Harrison (2015) argues that reconceptualizing heritage as an assemblage allows for a process of reassembling the practices responsible for its production, resulting in the production of new knowledges; or as Harrison (2015: 24, 28) refers to them, "new heritage ontologies," which enact new or alternative pasts, presents, and futures to privilege particular philosophies and economic, social, or political interests. Above all, Harrison (2015: 37) argues that describing, disassembling, and understanding the practices responsible for the production of heritage is the first step towards reassembling practice to allow for new or alternative heritage ontologies. This proposition has, however, been challenged more recently by Wiltshire (2017) who maintains this argument does not recognize the ongoing resistance, engagement, influence, and agency of Indigenous peoples in actively reassembling these disciplines, their practices, and the knowledges they produce.

Gavin Lucas (2012) and Chris Fowler (2013) have also sought to reconceptualize archaeological practice as an assemblage in order to address another persistent dichotomy: the dichotomy between archaeological theory and practice. Accordingly, Lucas (2012: 1) maintains particular archaeological practices remain accepted or normalized, informed by a positivist assumption that such practices represent an objective and linear process of data collection. Furthermore, Lucas (2012: 239) argues:

> . . .the process of translation that archaeologists routinely use today are so taken for granted that they appear obvious and unproblematic. . .we no longer need to worry about them how or why they work, we just use them. . .

This positivist assumption not only justifies the ongoing use of these practices, but ensures archaeological practice to remains sheltered from theoretical reflection. To address the persistent dichotomy between theory and practice, Lucas (2012) and Fowler (2013) reconceptualize archaeological practice as an assembling that comprises artifacts, people, and equipment, discussing the ways an archaeologist plays an active role in producing and shaping the nature of archaeological knowledge. In doing so, these authors seek to challenge the positivist assumption that knowledge production results purely from objective observations, in turn challenging the premise of theory-practice dichotomy.

Lastly, recent research by Hamilakis (2017) has sought to move away from the material, nonhuman focus emphasized by other applications of assemblage thinking within the archaeological discipline, to illuminate some of the agency of intangible sensorial, affective, and emotional actors that exist as part of an assemblage. In particular, Hamilakis (2017) discusses an archaeological feature in West Crete associated with a series of communal feasting

events, which he interrupts as a "sensorial assemblage" where affective memories evoked and produced play an important role in the assemblage that comprises large scale eating and drinking events. Similarly, recent research undertaken in southern Australia by Liebelt (2016) and Wiltshire (2017) has also sought to highlight some of the contemporary emotions that mediate the connection between people and archaeological traces. In particular, Liebelt (2016) explores non-Aboriginal people's emotional responses and attachment to Aboriginal heritage located on rural properties, whereas Wiltshire (2017) uses auto-ethnography to highlight emotions experienced as archaeologist that are usually obscured from linear accounts of archaeological practice.

Asses/Donkeys: Domestication

Fiona Marshall
Department of Anthropology, Washington University in St. Louis, St. Louis, MO, USA

Basic Species Information

Ancient African wild asses (*Equus africanus* Fitzinger, 1857) are the wild ancestors of donkeys (Beja-Pereira et al. 2004; Kimura et al. 2011). There are two living subspecies of African wild asses, Somali wild asses (*Equus africanus*

somaliensis Noack, 1884; Synonym: *E. a. somalicus* Sclater, 1884) and Nubian wild asses (*Equus africanus africanus* von Heuglin and Fitzinger, 1866). Somali wild asses or Dibokali are critically endangered (Moehlman et al. 2008). Nubian wild asses of Sudan and the Eritrean Red Sea Hills may now be extinct (Kimura et al. 2011; Moehlman et al. 2008). Atlas wild asses (taxonomy unclear so-called *Equus africanus atlanticus*) were distributed in northwestern Africa until Roman times.

Somali wild asses have shiny grayish coats; white muzzles, belly, and legs; and dark stripes on their lower legs. They do not have dark shoulder-crosses (Moehlman et al. 2008). In contrast, Nubian wild asses have variable shoulder-crosses and no leg-stripes. African rock art and Roman mosaics suggest that Atlas wild asses had both leg-stripes and shoulder-crosses (Marshall 2007). African wild asses are desert adapted, and in keeping with this, domestic donkeys have labile metabolic rates and water sparing mechanisms. Domestic donkeys are predominantly gray with a bold shoulder-cross and no leg-stripes. Although considerable regional variability exists, donkey coat colors are not greatly varied and breed diversity is minimal.

Genetic research has shown that there are two mitochondrial haplogroups of domestic donkeys worldwide, referred to as Clade I and Clade II, and that variability is greatest in northeastern Africa (Beja-Pereira et al. 2004). On the basis of these data, the distribution of ancient cattle herders across northeast Africa and linguistic evidence from northeast Africa, scholars have argued that Saharan pastoralists domesticated donkeys – perhaps more than once (Blench 2000; Beja-Pereira et al. 2004; Marshall 2007). Similarities in mitochondrial haplotypes demonstrate that the ancient Nubian wild ass is the ancestor of Clade I donkeys. Indeed, some of the haplotypes of historic Nubian wild asses sampled from the Sahara and Sudan are identical to those of modern donkeys of Clade I, suggesting that they may be related to the ancestral populations from which the wild ass was domesticated (Kimura et al. 2011). It is yet unclear, however, which historical population of African wild ass was the maternal ancestor of Clade II donkeys. Analysis of 440 bases of the mitochondrial control region showed that Somali wild asses are separated from Clade II donkeys by at least 12 mutations, and to date, ancient DNA has not been recovered from Atlas wild asses (Kimura et al. 2011). Coalescence analysis suggests, however, that the divergence among ancient Nubian wild asses, Somali wild asses, and the ancestor of Clade II donkeys goes back ~100,000 years and that maternal domestication processes were operating on at least two ancient populations or subspecies.

Domestic donkeys occur in archaeological sites as early as >5000 years ago in Southwestern Asia, and as a result, this has also been suggested as a region of domestication (Vila 2006). To date, however, there is no clear evidence that the African wild ass existed in southwestern Asia prior to the Holocene (Marshall 2007; Kimura et al. 2011). Nevertheless, Asia was an important center for ceremonial and trade-based use of donkeys (Vila 2006). Genetic data demonstrate that the wild ass of the region, the onager (*Equus hemionus*), was not an ancestor of the donkey (Beja-Pereira et al. 2004). Ancient texts and osteological analyses indicate, however, that Sumerians bred their donkeys with wild onagers and that these hybrids were used to pull chariots (Vila 2006; Weber 2008). Subsequently, female horses were bred with male donkeys to produce another hybrid – the mule. Mules are stronger than donkeys and still used today, but they are not fertile and do not produce offspring.

Domestication of the donkey was slow and complex. This process was influenced by the behavior of African wild asses and by use of donkeys for transport rather than for meat (Marshall and Weissbrod 2011). African wild asses do not fit traditional profiles for domestication; they have a fission-fusion social system with long-term bonds only between females and their foals (Moehlman et al. 2008; Marshall and Weissbrod 2011). Dibokali breed well in captivity but, in keeping with their social organization, display fewer affiliative behaviors than more

social equids such as horses. As a result of behavior and management patterns, donkeys in Africa and Asia are seldom intentionally bred (Marshall and Weissbrod 2011) and have many characteristics of their wild ancestors. Nevertheless, donkeys are more social than wild asses and breed younger. Like other domestic animals, donkeys are also smaller and have proportionally smaller brains than their wild ancestors. Donkeys did not decline in size, however, until late in the domestication process (Rossel et al. 2008).

Archaeology suggests that donkeys were domesticated by 6000–5000 years ago. Egyptian sites of Maadi and El Omari date to ~4500 BCE and Abydos to 3000 BCE. Domestic donkeys were present in southwest Asia by >3000 BCE (Vila 2006). At Abydos, animals buried in a royal mortuary complex were skeletally indistinguishable from African wild ass, but vertebral and limb pathologies demonstrated that they were used for transport (Rossel et al. 2008). Research on modern pastoralist donkey management has helped to explain selection during donkey domestication by showing that herders value donkeys with the size, strength, and hardiness of their wild ancestor (Marshall and Weissbrod 2011). There is little impetus for controlled breeding and reasons to counteract the effects of selection in anthropogenic environments and genetic drift by breeding domestic donkeys with wild asses. As transport animals, early donkeys played a major role in the creation of ancient trade routes in northeast Africa and Asia, were ritually and politically significant, and played an important role in the development of mobile African herding societies. Donkeys are widely relied on today for household transport and trade in arid and poorer regions of the world (Rossel et al. 2008).

Association for Environmental Archaeology (AEA)

Meriel McClatchie
School of Archaeology, University College Dublin, Dublin, Republic of Ireland

Association for Environmental Archaeology (AEA), Fig. 1 Association for environmental archaeology logo

Basic Information

The Association for Environmental Archaeology (AEA) (www.envarch.net) (Fig. 1) is an international organization that promotes the study of human interactions with environments through archaeology and related disciplines. The AEA was originally established in 1979 to encourage communication between workers in environmental archaeology in the UK but has since become more international in its outlook – more than one-quarter of its approximately 400 members currently live outside the UK, mostly in Europe, but also USA, Canada, Asia, and Australia. Members' interests are wide ranging, including archaeobotany, zooarchaeology (both vertebrate and invertebrate), geoarchaeology, paleoecology, and biological anthropology, as well as related fields, such as ancient economies. Membership is open to all, including university, museum, government, and commercially based workers, as well as research students and nonprofessionals with an interest in environmental archaeology. In addition to individual membership, institutional membership is also available. Honorary members are appointed on occasion to recognize persons who have made a major contribution toward the aims of the Association.

Major Impact

The AEA is one of the largest organizations of environmental archaeologists in the world. A major output is its international peer-reviewed journal, *Environmental Archaeology: The Journal of Human Palaeoecology* (http://www.tandfonline.com/loi/yenv20). Four issues are currently published each year and sent to all members. The journal contains papers on a variety of aspects of environmental archaeology, including methodology, synthesis, and theory. The journal publishes substantial research papers and shorter reports, focusing on new techniques, philosophical discussions, current controversies, and suggestions for promising directions of research. Critical reviews of recent academic publications are also published in a book review section. Taylor and Francis took over publication of the journal in 2015; prior to this, the journal was published by Oxbow Books and Maney Publishing. The current AEA journal, *Environmental Archaeology*, was launched in 1997. The previous journal of the AEA was *Circaea*, of which 12 volumes were published between 1983 and 1996. All volumes of *Environmental Archaeology* and *Circaea* are currently available online to AEA members.

Two AEA conferences are held each year, which are open to all, and conference bursaries are available to members to enable attendance. The spring event is often a 1-day meeting, while the autumn event is usually a major conference. These meetings are designed to keep members up to date with recent advances and new approaches in environmental archaeology. Meeting locations in recent years include Britain, Denmark, Germany, Japan, Ireland, Italy, the Netherlands, and Poland. The 1-day meeting often includes short papers on work in progress and provides an opportunity for research students to present data. Papers presented at the annual conference are often more substantial and focused on a particular theme. In the past, conference proceedings have been published in monograph form, including

volumes on subsistence, specialization and surplus (Groot et al. 2013), environmental archaeology of industry (Murphy and Wiltshire 2002), human settlement and marginality (Coles and Mills 1998), taphonomy (Huntley and Stallibrass 2000), and economies and environments in the North Atlantic region (Housley and Coles 2004). Collections of papers from conferences have also appeared as special issues of the journal, for example, *Worlds Apart? Human Settlement and Biota of Islands* and *Environmental Archaeologies of Neolithisation*. The AEA organizes a seminar series, which sponsors and publicizes individual seminars at different institutions on any aspect of environmental archaeology. A Small Research Grants Scheme was established in 2015, and the AEA administers the "John Evans prize," an annual competition for the best undergraduate and postgraduate dissertations on any aspect of environmental archaeology, which is open to students across the world. An AEA Archaeological Society Membership Prize has also been established to recognize the contribution of local archaeological societies to environmental archaeology.

The AEA newsletter is published quarterly each year, and together with the website, they keep members informed about new research, relevant meetings and conferences, recent publications in environmental archaeology, job opportunities, and external websites and organizations. An AEA Discussion List (ENV-ARCH) has been established via JISC mail to encourage members from a variety of backgrounds to pose questions and discuss their work in a wider forum. The AEA has also published working papers on the teaching of environmental archaeology in UK higher education and on environmental archaeology and archaeological evaluations in England, which are available from the AEA website.

The affairs of the AEA are governed by its constitution and handled by an elected Management Committee, which consists of a Chair, Secretary, Treasurer, Membership Secretary, Journal Editor, Newsletter Editors, Conference Officer, Publicity Officer, Website Officer, Prize Administrator, Bookclub Administrator, Grant Administrators, Student Representatives, and Ordinary Members.

Association for Industrial Archaeology (AIA)

Marilyn Palmer
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Basic Information

The Association for Industrial Archaeology (AIA) grew out of a number of conferences organized at the University of Bath in the UK in the early 1970s. Since its first formal meeting in 1973, AIA has since grown to become the foremost national organization for people who share an interest in the UK's industrial archaeology and industrial heritage. From the beginning, it has been an organization in which the amateur and the professional meet. Although the discipline of industrial archaeology was first championed by the Council for British Archaeology (CBA) and supported by many professional archaeologists, the early recording work on industrial sites was carried out by volunteers and they still form the main body of the association. Much of the recording was carried out by groups of people in the individual counties, and the AIA, early in its existence, decided to introduce a category of membership for affiliated societies, and so the AIA represents a far larger number of people than its individual membership, amounting to several thousand. The AIA holds an annual meeting for members of its affiliated societies as well as inviting them to its annual conference.

The AIA recognizes high standards of survey, interpretation, and publication by a number of awards to both professional and amateurs each year, as well as making grants for the restoration of industrial sites by volunteers. An international refereed journal, *Industrial Archaeology Review*, has been produced twice a year since 1977 (Palmer 2018). Members receive an illustrated newsletter four times a year as well as a gazetteer of industrial sites in whichever region the annual conference is held: now numbering over 30, these provide a useful list of sites of industrial interest in the UK. Further details concerning these and other activities can be found on the association's website: http://industrial-archaeology.org/. The AIA's liaison office is based at the Ironbridge Institute, Ironbridge Gorge Museum, Coalbrookdale, UK. The association has a governing council elected on an annual basis. At the time of writing, the association's chairman is Dr. Michael Nevell, the secretary is David de Haan, and treasurer is John Jones. The current honorary president is Professor Marilyn Palmer, and former incumbents include Tom Rolt, Professor Angus Buchanan, and Sir Neil Cossons, several of whom now serve as honorary vice-presidents.

Major Impact

The AIA has always tried to champion the cause of industrial archaeology and the industrial heritage at the national level and has worked closely both with the CBA and with national organizations such as English Heritage, Historic Scotland, and Cadw. In 1991, the AIA launched a pamphlet, *Industrial Archaeology: Working for the Future*, which was essentially an examination of the scope of industrial archaeology and a set of research priorities, with recommendations for urgent action. These found their way unto various strategy documents produced by English Heritage. This was supplemented in 1993 by a research project, the Index Record of Industrial Sites, aimed at the creation of a national database of industrial sites, which inter alia produced a set of terms for the components of such sites. These were incorporated into the national Thesaurus of Monument Types as well as being used locally to record industrial sites into county sites and monument records. Further efforts were made to influence national strategies in industrial archaeology in several ways, especially by a conference resulting in the publication of a research strategy in 2005, *Understanding the Workplace: a Research Framework for Industrial Archaeology in Britain*. The AIA has also, for many years, run a seminar for professional archaeologists on current research and thinking in industrial archaeology prior to its annual conference. Specific topics for this seminar have included the defense heritage,

urban regeneration and the adaptive reuse of industrial buildings, and the recording and excavation of twentieth-century sites. Between 2008 and 2011, the AIA, in conjunction with the CBA, ran 11 training schools in each of the English Heritage regions in an effort to train those who had responsibility for local planning to understand the significant features of industrial sites and structures so that these could be retained in the process of adaptive re-use. This resulted in a further publication, *Industrial Archaeology: A Handbook* (Palmer et al. 2012).

Association Internationale pour l'Histoire du Verre (AIHV)

Jane Shadel Spillman
The Corning Museum of Glass, Corning, NY, USA

Basic Information

The Association Internationale pour l'Histoire du Verre (AIHV) was founded by Joseph Philippe in 1956 as the Journées Internationales d'Histoire du Verre. He was then the Director of the Musée Curtius in Liège, Belgium, and he organized the first congress of the AIHV, which was held in that city in 1958. Seventeen congresses have been held, at about 3-year intervals, since that time, in Leyden, Damascus, Ravenna–Venice, Prague, Cologne, Berlin–Leipzig, London–Liverpool, Nancy, Madrid–Segovia, Basel, Vienna, Amsterdam, Venice–Milan, New York City–Corning, London, Antwerp, and Thessaloniki. The 19th congress took place September 17–21 in Piran, Slovenia, followed by a post-congress tour September 22–23 to Croatia.

Major Impact

In addition to hearing about new research in glass, congress participants can view special exhibitions and visit museums, galleries, and private collections. The congresses also provide AIHV members an opportunity to meet their colleagues from other countries. Those members include several hundred archaeologists, art historians, artists, collectors, museum curators, *graduate students, scientists, and researchers from more than 30 countries*. Papers presented at AIHV congresses are published in the organization's *Annales*. From 1958 to 1983, the association also published bulletins that included information about glass collections in various countries, usually where the congresses were located.

The AIHV was reorganized in 1983, when it adopted its current name. It is now governed by statutes under Dutch law as it was headquartered

in the Netherlands at that time. The president and the board of directors are elected for 3-year terms. The general secretary is appointed by the board and serves as long as he or she is willing. The official languages are English, German, and French, and papers may be presented in any of these languages at the congresses. For other communications to members, only French and English are employed.

Membership in the AIHV is open to all. Students are admitted free of charge. For all others, the annual subscription fee includes a copy of the *Annales*.

Asylum, Human Rights, and Cultural Heritage

Federico Lenzerini
Department of Political and International Sciences, University of Siena,
Siena, Italy

Definitions

Asylum — Pertinent international legal instruments do not include any definition of "asylum." However, it may be defined as "the protection granted by a sovereign State on its own territory to an alien (or stateless person) who has been forced to leave the country of her/his nationality (or habitual residence) due to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion." This definition is directly drawn from Article 1A(2) of the 1951 Geneva *Convention relating to the Status of Refugees* (Geneva Convention), on account of the substantial coincidence existing between "asylum" and "protection of refugees."

Human Rights — Human rights are the rights and freedoms inherent to all human beings – for the whole length of their existence – regardless of race, color, sex, nationality, ethnic origin, language, religion, or any other status or condition. Human rights are all interrelated, interdependent, and indivisible.

Cultural Heritage — In international law there is no univocal, universally accepted definition of "cultural heritage." The existing pertinent international conventions include their own working definitions, which – although expressed in similar terms – vary depending on the specific purposes pursued by each relevant instrument. However, the cultural heritage of a people may be considered as including "the works of its artists, architects, musicians, writers and scientists and also the work of anonymous artists, expressions of the people's spirituality, and the body of values which give meaning to life. It includes both tangible and intangible works through which the creativity of that people finds expression: languages, rites, beliefs, historic places and monuments, literature, works of art, archives and libraries" (UNESCO *Mexico City Declaration on Cultural Policies*, 1982). Cultural heritage may be of either material or intangible character,

as well as a combination of both tangible and intangible expressions. For most elements of cultural heritage, it is impossible to dissociate their tangible and intangible components.

Introduction

Asylum is one of the most ancient social and legal phenomena of human history. As a legal institute, it represents a direct emanation of the need of human beings to be protected against the dangers threatening their life, which is inherent in human nature.

Asylum is strictly intertwined with human rights under a threefold perspective. First, the right to asylum is considered itself a human right, proclaimed inter alia by Article 14 of the *Universal Declaration of Human Rights* (1948). Secondly, asylum is usually invoked – and eventually granted by the requested State – in order to prevent serious breaches of the human rights of the asylum-seeker. Thirdly, an asylee (i.e., a person to whom asylum has been granted) in a foreign country is entitled to protection of her/his fundamental human rights, including those guaranteed by relevant international conventions.

An asylum-seeker obtaining protection in a foreign country is usually disconnected from her/his cultural heritage, which normally represents an essential component of her/his cultural identity and, hence, a very significant element of her/his existence. Therefore, the problem arises of whether and to what extent, in legal terms, the right of asylees to cultural heritage is today guaranteed.

Historical Background

Although with changing fortunes, asylum has always had a place in human history. It first developed especially as a *religious* phenomenon, characterized, since the times of Ancient Greek, by the inviolability of the temple, where all or certain categories of human beings (depending on the different epochs of Greek history) could find shelter. The impact of asylum on social life drastically decreased in the age of the Romans, when the rule of law was strongly entrenched in the society and asylum was seen as an obstacle to the just administration of justice. With the fall of the Roman Empire, religious asylum knew its brightest season, as it often was the only existing defense against the legal disorder characterizing most territories in Europe; its importance progressively grew in parallel with the extension of the secular power acquired by the Christian Church. From the fourth to the tenth centuries AD, religious asylum was considered as a natural and inalienable right of the human being. Its use was strongly promoted by the Church, as it increased its power on, and control of, temporal affairs. Only in the sixteenth century, after a few centuries during which its legitimacy was challenged by the holders of the secular power, religious asylum started to decline, leading to its progressive and inexorable downfall, although it continued to be practiced up to the XX Century. In the meantime, with the development and stabilization of the idea of "State" and the embryonic manifestations of the concept of "territorial sovereignty" – in the context of which law was progressively replacing religion in the government of temporal affairs – the connotation of asylum which prevailed was the *territorial* one, conceived as expression of the inviolability of the territories where the different human communities were politically organized. Asylum then started to take the modern connotation of the term. On the one hand, the awareness of the need to promote international cooperation in the repression of crimes progressively increased, resulting, since the beginning of the seventeenth century, in the development of extradition treaties aimed at ensuring prosecution of the authors of common crimes. On the other hand, and at the same time, as a result of the growing intolerance for freedom of thought and religion which characterized many absolute monarchies in Europe, asylum started to be perceived as the only shelter against tyranny for those who claimed their freedom to express their ideas, assuming the connotation of *political asylum*. The latter finally reached the status of

positive rule of customary law – at least among Western countries – in the nineteenth century, and its existence was authoritatively sanctioned by Article 14 of the *Universal Declaration of Human Rights* (1948), which states that: "(1) Everyone has the right to seek and to enjoy in other countries asylum from persecution. (2) This right may not be invoked in the case of persecutions genuinely arising from non-political crimes or from acts contrary to the purposes and principles of the United Nations." Such a provision, however, did *not* recognize a right of asylum-seekers to *obtain* protection in a foreign country in case of persecution, but only their right to *request* asylum. States retained their unconditioned discretion to decide whether or not the benefit had to be granted, while, in the event that the request of asylum was accepted, it could not be considered as an unfriendly act by the State of origin of the asylee (Lenzerini 2009). In the meantime – particularly from the XIX Century – also the practice of granting asylum in foreign embassies and consulates notably developed, especially in Latin America, leading *diplomatic asylum* to attain the status of local custom in force for the majority of Latin American countries (Francioni 1973).

The generally unrestricted freedom of States to decide whether or not asylum had to be granted, irrespective of the circumstances characterizing the personal situation of the asylum-seeker, started to be constrained in the twentieth century, thanks to the adoption of international multilateral treaties regulating the matter. The most important of such treaties is undoubtedly the Geneva Convention, which at Article 1A(2) defines a refugee as a person who, "[a]s a result of events occurring before 1 January 1951 and owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear, is unwilling to return to it." The temporal limitation established at the beginning of the definition was removed by the 1967 New York *Protocol relating to the Status of Refugees*, by virtue of which the provisions of the Convention became of general application. Article 33 of the Convention proclaims the principle of *nonrefoulement*, stating that "[n]o Contracting State shall expel or return ('refouler') a refugee in any manner whatsoever to the frontiers of territories where his life or freedom would be threatened on account of his race, religion, nationality, membership of a particular social group or political opinion." This principle has later elevated to the status of rule of customary international law (Lenzerini 2009).

Key Issues and Current Debate

While some of the major host countries of asylees base their practice of granting asylum on their historical traditions of hospitality (two of the four major host countries of refugees – i.e., Pakistan and Lebanon (see Fig. 1) – have not even ratified the Geneva Convention), at the international level asylum is generally considered as corresponding to the protection accorded to refugees in application of the Geneva Convention and of the prohibition of *refoulement*, taking into account that the forms of protection subsumed within the scope of operation of "asylum" (intended in broad terms) may take diverse denominations in the different countries of the world.

At the end of 2017 the number of persons forcibly displaced (i.e., compelled to move from their locality and/or environment against their will) worldwide, hence in need of international protection, was 68.5 million. Such rate included 25.4 million refugees, 40 million internally displaced people, and 3.1 asylum-seekers (UNHCR 2017). More generally, during the last decade, the number of people in need of international protection has constantly increased (see Fig. 2).

In the absence of international obligations to share the burdens of asylum-seekers and refugees in situations of particular pressure for certain States, this increment determines situations of

Asylum, Human Rights, and Cultural Heritage, Fig. 1 Major host countries of refugees – © UNHCR (https://www.unhcr.org/globaltrends2017/)

Asylum, Human Rights, and Cultural Heritage, Fig. 2 Trend of global displacement and proportion displaced 2007–2017 – © UNHCR (https://www.unhcr.org/globaltrends2017/)

emergency in the territories most pressured by such flows, increasing the threats for the human rights of the people concerned, particularly for the reason that said States may hardly be capable and/or willing to adequately take care of them and provide to their basic needs. These situations represent huge threats to the realization of international human rights law. In fact, no reasonable doubts arise on the fact that asylum-seekers and refugees are entitled to the full measure of

internationally recognized human rights – including certain specific rights which are particularly necessary in light of their peculiar situation and needs. However, the fact of whether or not such rights include prerogatives related to cultural heritage – and especially the scope and extent of such specific rights – is more debatable.

International Perspectives

Asylum and Human Rights

The purpose of asylum – in its contemporary international connotation – is to guarantee protection in favor of persons having a well-founded fear of persecution and to prevent that their fundamental human rights are infringed. It follows that the human-rights-related implications arising from asylum and refugee protection may be categorized into three different ontological plains: (1) prohibition to deport asylum-seekers and refugees to countries where their fundamental human rights would be at risk (principle of *non-refoulement*); (2) guarantee of the enjoyment of fundamental human rights for asylum-seekers and refugees during the whole length of the procedure aimed at verifying the existence of the conditions necessary for the determination of refugee (or other equivalent) status; (3) assurance of the enjoyment of human rights during the whole period of time the person will remain in the territory of the country of asylum after the status of refugee (or other equivalent form of international protection) has been recognized.

As regards the principle of *non-refoulement*, it consists in the prohibition of deporting an asylum-seeker to a country where her/his fundamental human rights would be threatened. In practice, it is especially applied when the violation faced by the asylum-seeker would consist in instances of torture or inhuman or degrading treatment or punishment. However, it is also applicable to situations where other fundamental human rights – particularly right to life and freedom from slavery and servitude – are under threat. The prohibition in point corresponds to a State obligation existing not only within the territory of the country concerned, but extends to all areas where the government, through its organs or agents, effectively exercises its jurisdiction *de jure* and/or de facto. For instance, in the case of *Hirsi Jamaa and Others v. Italy* (Application No. 27765/09, judgment of 23 February 2012), the European Court of Human Rights (ECtHR) considered the respondent State responsible of a violation of Article 3 of the 1950 *European Convention on Human Rights* (prohibition of torture or inhuman and degrading treatment or punishment), for the fact that its navy had intercepted on sea a boat carrying several asylum-seekers, taken the latter on board and carried them to Libya, which was considered a dangerous country. Despite the fact that the whole event took place on the high seas, hence outside the sovereignty of whatever State, Italy was considered responsible of the violation because "the applicants were under the continuous and exclusive *de jure* and *de facto* control of the Italian authorities." Furthermore, the prohibition in point extends not only to *direct refoulement* (i.e., to cases when the asylum-seeker is *directly* deported to a dangerous country), but also to *indirect* one – which takes place when deportation occurs to a country which is safe in itself, but from which it is possible that the person is transferred to a dangerous State (see *Hirsi Jamaa and Others v. Italy*, para. 146). While para. 2 of Article 33 of the Geneva Convention excludes from protection against *refoulement* any refugee "whom there are reasonable grounds for regarding as a danger to the security of the country in which he is, or who, having been convicted by a final judgment of a particularly serious crime, constitutes a danger to the community of that country," similar provisions of more recent adoption – particularly Article 3 of the 1984 UN *Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment* – exclude that the prohibition in point may be the object of exceptions. Also, in its pertinent judgments, the ECtHR is used to reiterate that "the conduct of the person concerned, however undesirable or dangerous, cannot be taken into account, with the consequence that the protection afforded by Article 3 [of the European Convention on Human Rights] is broader than

that provided for in [Article] [...] 33 of the [Geneva Convention]" (see, inter alia, *Case of Saadi v. Italy*, Application No. 37201/06, judgment of 28 February 2008, para. 138).

During the procedure for the determination of refugee status (or other equivalent forms of international protection, including "subsidiary protection" provided for by EU Directive 2011/95/EU of 13 December 2011), asylum-seekers are to be considered as belonging to "a particularly underprivileged and vulnerable population group in need of special protection" (ECtHR, *Case of M.S.S. v. Belgium and Greece*, Application No. 30696/09, judgment of 21 January 2011, para. 251). The UNHCR Executive Committee has considered essential that "asylum-seekers who have been temporarily admitted pending arrangements for a durable solution should be treated in accordance with [certain] minimum basic human standards," which include the enjoyment of "the fundamental civil rights internationally recognized," the right to "receive all necessary assistance and be provided with the basic necessities of life including food, shelter and basic sanitary and health facilities," the right to be subjected to "no discrimination on the grounds of race, religion, political opinion, nationality, country of origin or physical incapacity," the right "to be considered as persons before the law, enjoying free access to courts of law and other competent administrative authorities," the right to respect for family unity, the right of minors and unaccompanied children to be granted special assistance, as well as the possibility to obtain "all the necessary facilities to enable them to obtain a satisfactory durable solution" for their situation (UNHCR Executive Committee 1981). With respect to detention of asylum-seekers, it is first of all to be noted that detention in itself is *not* a violation of human rights and international law in general. However, in order to be lawful, detention needs to respect very strict conditions. In particular, "detention may be resorted to only on grounds prescribed by law to verify identity; to determine the elements on which the claim to refugee status or asylum is based; to deal with cases where refugees or asylum-seekers have destroyed their travel and/or identity documents or have used fraudulent documents in order to mislead the authorities of the State in which they intend to claim asylum; or to protect national security or public order." Asylum-seekers must be protected against "unjustified or unduly prolonged detention." Detention measures taken in their respect "should be subject to judicial or administrative review," their conditions of detention must be humane, and they should "not be accommodated with persons detained as common criminals" or "be located in areas where their physical safety is endangered" (UNHCR Executive Committee 1986). In addition of respecting the said guarantees of fair treatment, in order to be "lawful" detention of asylum-seekers must not be arbitrary, meaning that it must "have a legal basis in domestic law," must be "compatible with the rule of law, a concept inherent in all the Articles of the [European] Convention [on Human Rights]," and the authorities' orders of detention must be "sufficiently accessible and precise, in order to avoid all risk of arbitrariness" (see ECtHR, *Case of Amuur v. France*, Application No. 19776/92, judgment of 25 June 1996, para. 50).

After the recognition of refugee status, granting of subsidiary protection or any other equivalent form of protection that may be accorded at the domestic level, the person concerned is obviously entitled to the full measure of internationally recognized human rights, to the same extent of any other human being. More specifically, refugees are explicitly attributed certain rights by the Geneva Convention, including the following: right to acquire movable and immovable property, and other rights pertaining thereto, according to a treatment not less favorable than that accorded to aliens generally in the same circumstances (Article 13); right to protection of industrial property, including inventions, designs or models, trademarks, trade names, as well as rights in literary, artistic, and scientific works, to the same level as is accorded to nationals of the country of asylum (Article 14); right of association (regarding nonpolitical and nonprofit-making associations and trade unions), with the guarantee of "the most favorable treatment accorded to nationals of a foreign country, in

the same circumstances" (Article 15); right of access to courts (Article 16); right to engage in wage-earning employment, with the guarantee of the most favorable treatment accorded to nationals of a foreign country in the same circumstances (Article 17); right to self- employment "in agriculture, industry, handicrafts and commerce and to establish commercial and industrial companies," according to a treatment "not less favorable than that accorded to aliens generally in the same circumstances" (Article 18); right of access to liberal professions, granting them a treatment "not less favorable than that accorded to aliens generally in the same circumstances" (Article 19); right to housing, again with the guarantee of a treatment "not less favorable than that accorded to aliens generally in the same circumstances" (Article 21); right to access to elementary education, with the guarantee of "the same treatment as is accorded to nationals" (Article 22); right to be granted "the same treatment with respect to public relief and assistance as is accorded to [. . .] nationals" (Article 23); labor rights and right to social security, according to the conditions established by Article 24; right to administrative assistance (Article 25); right to freedom of movement, "subject to any regulations applicable to aliens generally in the same circumstances" (Article 26); right to receive identity papers (Article 27) and travel documents (Article 28); right to transfer assets brought into the territory of the host State (Article 30).

A "Right to Cultural Heritage" for Asylees?

Among the rights explicitly recognized in favor of asylees, no mention is made to a "right to cultural heritage." Such a right is normally not even contemplated in human rights treaties as a right generally attributed to human beings, although, as explained below, some of such treaties provide for certain cultural rights of migrants. This said, it is indubitable that cultural heritage determines notable implications in terms of human rights. Cultural heritage is "intertwined with identity and territory" (Silverman and Ruggles 2007), and it "is impossible to separate a people's cultural heritage from the people itself and that people's rights" (UN Special Rapporteur in the field of cultural rights 2016). Safeguarding the connection between individuals or communities and their own cultural heritage is an indispensable prerequisite for ensuring their effective enjoyment of a number of human rights, including (but not limited to) right to religion, freedom of expression, right of minorities to enjoy their own culture, right to take part in cultural life – which includes the right "to benefit from the cultural heritage and the creation of other individuals and communities" (Committee on Economic, Social and Cultural Rights 2009) – right to cultural identity, as well as right to property (Lenzerini 2019). The very concept of *human dignity*, "which informs [. . .] human rights [. . .] includes peoples entitlement to the respect of the cultural heritage that forms an integral part of their identity, history and civilization" (Francioni 2004). This position is confirmed by the practice of human rights monitoring bodies. For instance, the African Commission on Human and Peoples' Rights has affirmed that "[p]rotecting human rights [. . .] requires respect for, and protection of, [the] religious and cultural heritage essential to [a] group identity" (*Centre for Minority Rights Development (Kenya) and Minority Rights Group International on Behalf of Endorois Welfare Council v. Kenya*, Communication 276/2003, May 2009, para. 141). In the end, it is reasonable to assert that today a *right to cultural heritage* exists under international law (Orser 2007; Alderman 2013), in the form of an implied right arising from the concrete operation of several human rights explicitly recognized by relevant international instruments.

The next question to be addressed is whether and to what extent such a right to cultural heritage applies to asylees. This question is relevant under at least three different profiles.

First, it may be reasonably assumed that asylees, like other categories of migrants and/or members of diasporas, have the right to preserve their connections with the cultural heritage located in their original homeland (Orser 2007; Committee on Economic, Social and Cultural Rights 2009), especially as regards the heritage which is particularly significant for their cultural

identity. Article 31 of the 1990 *International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families* militates in favor of this conclusion, affirming that "States Parties shall ensure respect for the cultural identity of migrant workers and members of their families and shall not prevent them from maintaining their cultural links with their State of origin." An equivalent provision is included in Article 12(f) of ILO Convention No. 143 of 1975 *concerning Migrations in Abusive Conditions and the Promotion of Equality of Opportunity and Treatment of Migrant Workers*. Similarly, Article 5 of the 1995 Council of Europe's *Framework Convention on the Protection of National Minorities* requests States parties "to promote the conditions necessary for persons belonging to national minorities to maintain and develop their culture, and to preserve the essential elements of their identity, namely their religion, language, traditions and cultural heritage". However, while it is not reasonably deniable in principle, the conclusion in point triggers concrete questions which are hardly answerable a priori, e.g., how long (i.e., for how many generations) the right in point continues to exist, or whether and to what extent asylees or other migrants have rights as regards decisions about the management and use of cultural properties in their (and their ancestors') original homeland (Orser 2007; Blake 2015).

Secondly, asylees – like other categories of migrants – have the right to transfer their own cultural property in the country of asylum, as well as, in principle, to establish there their own cultural (particularly religious) institutions. This is a necessary implication of the right of migrants to have their cultural identity preserved (Committee on Economic, Social and Cultural Rights 2009). In the last decades, "forms of cultural expression have flourished in urban areas [of many countries], under the impetus of communities descended from immigrant families," also with the aim "to maintain links with the countries of origin" (Wihtol de Wenden 2007). Examples described in literature include, among others: the Russian-Lipovans, cruelly persecuted since the seventeenth century and forced to flee in several European countries, including Spain, particularly the Basque country, and Italy, where they have imported their Orthodox Church's ancient heritage (Vlaskina 2017); the over 30,000 Chilean refugees who escaped to Sweden since 1973, fleeing the cruelties of the Pinochet regime and producing "a lot of tangible and intangible heritage" in the host country (Colomer 2013); the Tibetan refugee community living in India since the 1950s, the members of which have carried "with them a rich cultural heritage" (Adams 2005); and the cultural group Tadiazt, who fled from Mali and settled in Mberra refugee camp, in Mauritania, where they "perform their traditional songs in the camp in order to keep their oral culture alive and to transmit it to the young people living in the camp" (Chechi 2016).

The third profile concerns the question whether asylees acquire any right over the cultural heritage belonging (in cultural terms) to the country of asylum and to other human communities living therein, in the sense of obtaining a decisional role in the context of the management of such a heritage. In principle this is to be excluded – as "perhaps simply inhabiting a region should not automatically bestow heritage rights" (Orser 2007) – at least until when they fully integrate in the host country and may be considered as being part of its social and cultural milieu. However, this can in no way affect their entitlement to protection of cultural rights, their right to take part in cultural life, and their right to enjoy their own intangible cultural heritage. In fact, "cultural rights and cultural heritage preservation can play [a decisive role] in the integration and rehabilitation of refugees and displaced persons after trauma" (UN Secretary General 2016). In many cases, refugees turn "to various forms of [intangible cultural heritage and] cultural expressions that help them live through disasters [. . .] Within new environments, the performing arts or crafts skills can [. . .] provide a source of livelihood, whereas traditional knowledge may be harnessed for survival" (Chatelard 2017). At the same time, the right "to benefit from the cultural heritage and the creation of other individuals and communities" (Committee on

Economic, Social and Cultural Rights 2009) – more generally, to have access to multiple heritages – and, specifically, the possibility to enjoy the cultural heritage of the host country, may be fundamental in order to favor integration of asylees in such country.

Future Directions

While the existence of cultural-heritage-related rights of asylees may be drawn from a systematic and ontological interpretation of international human rights law, today the process towards guaranteeing the effective realization of such rights is still at an embryonic level. The speeding-up and strengthening of this process is first of all necessary in the interest of asylees themselves – as the lack of effectiveness of such rights, in addition to the denial of their internationally recognized human rights, "may bring about [their] marginalisation [. . .] and the concealment of their heritage practices from the public sphere" (Chechi 2016), as well as, eventually, the loss of their distinctive cultural identity. Also, the lack of adequate national policies aimed at ensuring the effective realization of rights to cultural heritage of asylees certainly hinders their successful integration into the social environment of the country of asylum. At the same time, countries of asylum and the international community as a whole would also greatly benefit from the promotion of such rights, for the reason that asylees may provide a huge contribution to the preservation of cultural heritage and to the promotion of pluralism and cultural diversity (Chechi 2016). Surely, to make this possible, it is necessary to foster the awareness that, in the States of asylum, "today national identity comprises another component" (Wihtol de Wenden 2007), i.e., migrants in general and asylees in particular.

Atalay, Sonya

Eleanor Jenkins
Parkville, VIC, Australia

Basic Biographical Information

Dr. Sonya Atalay is a Native American (Anishinabe-Ojibwe) anthropologist and archaeologist and a prominent advocate for community-based and participatory research (CBPR). Dr. Atalay is one of the first of her people to undertake tertiary studies in archaeology.

Atalay grew up in Michigan. She completed her B.A. in Anthropology and Classical Archaeology at the University of Michigan, Ann Arbor, in 1991. In 1997 Atalay first undertook field excavations at the site of Çatalhöyük in Turkey, analyzing clay and ceramics to investigate prehistoric cooking practices. She completed her M.A. in Anthropology at the University of California, Berkeley, in 1998.

In 2003, Atalay obtained her Ph.D. in Anthropology at UC Berkeley. Subsequently, she has been awarded the positions of UC Berkeley President's Postdoctoral Fellow (2003–2005) and Stanford University's NSF Postdoctoral Scholar (2005–2007). From 2007 to 2012, Dr. Atalay held the role of Assistant Professor in the Department of Anthropology at Indiana University as well as Adjunct Assistant Professor in American Studies, Near Eastern Languages and Cultures, and Central and Eurasian Studies. She is currently Assistant Professor at the University of Massachusetts, Amherst, in Anthropology and the Commonwealth Honors College.

Dr. Atalay is a member of the Society for American Archaeology, the American Anthropological Association, the World Archaeological Congress and the Native American and Indigenous Studies Association. She has served as Chair of the Society for American Archaeology Committee on Native American Relations, as well as the Society for American Archaeology Indigenous Populations Interest Group. She was one of the founding board members of the Coalition for Indigenous Archaeology. Dr. Atalay is also a first degree Midewiwin of the Three Fires Midewiwin Society, concerned with maintaining traditional knowledge and spiritual teachings of the Anishinabe people.

Major Accomplishments

Dr. Sonya Atalay has made important and inventive contributions to the field of community archaeology. She began working at Çatalhöyük analyzing clay materials (Atalay 2005) but became increasingly interested in broadening the local community's involvement on-site. In 2005, Dr. Atalay launched the Çatalhöyük community-based participatory research (CBPR) program (Atalay 2012). Instead of only employing local residents as excavation labor and ethnographic informers, Atalay's new project sought to engage locals on an equal level to the archaeologists, as collaborators and research partners. With local communities consulted about the sorts of participation they desire, the Çatalhöyük CBPR project has grown to include an annual festival, a theater group, production of comic books and newsletters, and archaeological lab-guide training for local children and teens. Particular effort has been put into increasing archaeological and scientific literacy among local communities, which has led to opportunities for internship positions and joint authorship for locals. Dr. Atalay characterizes her approach to community archaeology as

being "by and with" local communities, instead of "on and for" (Atalay 2010).

Dr. Atalay seeks to demonstrate that community archaeology methods are applicable worldwide. To this end she has worked in collaboration with a number of Native American communities in Michigan and Indiana. Dr. Atalay has worked with the Sullivan County American Indian Council to produce geographical and oral history surveys of the Waapaahsiki Siipiiwi Mound in Fairbanks, Indiana. This project includes the development of an interpretive walking trail around the mound to help protect the site and educate visitors. Since 2009, Dr. Atalay has assisted an initiative by the Ziibiwing Center of the Saginaw Chippewa Indian Tribe of Michigan to protect the Sanilac petroglyphs site. This involves seeking protection not only for the fragile petroglyphs themselves but also for the indigenous intellectual property they represent. The project has been funded as a case study by the Intellectual Property Issues in Cultural Heritage project (IPinCH). Dr. Atalay is assisting with the implementation of a tribal management plan to ensure that traditional owners decide how investigations of the site are conducted, as well as how widely documentation of this sacred knowledge may be shared.

A significant focus of Dr. Atalay's work has been on the decolonization of archaeology. Invited to guest-edit an issue of *American Indian Quarterly*, Dr. Atalay featured articles on the subject of decolonization and offered her own critique of the National Museum of the American Indian and its approach to presentation (Atalay 2006). Since 2004, Dr. Atalay has researched issues of cultural preservation and repatriation surrounding the Native American Graves Protection and Repatriation Act (NAGPRA). This includes investigation of human remains classified as "culturally unidentifiable" as well as Dr. Atalay's role as Coprincipal Investigator for the Stone Street Recovery and Mitigation Project. She has worked with the Saginaw Chippewa Indian Tribe towards documenting ancestral remains held by the University of Michigan, with the ultimate aim of repatriation due to begin in late 2012. Dr. Atalay was appointed to NAGPRA's review committee in 2009.

From 2007 to the present, Dr. Atalay has taught undergraduate and graduate classes in Anthropology at Indiana University, topics ranging from food archaeology to NAGPRA and CBPR methods. In keeping with her commitment to making academic work more widely accessible, she has also made many presentations on public archaeology for school-aged children.

Atlantic Ocean: Maritime Archaeology

David J. Stewart
Program in Maritime Studies, East Carolina University, Greenville, NC, USA

Introduction

Maritime archaeologists have never conceived of the Atlantic as a unified subject for study in the same way that Atlantic world historians have. While much maritime archaeological work has been done beneath the surface of the Atlantic Ocean, those doing the projects have typically pursued them in reference to their own particular research interests and questions rather than seeing such research as part of a unified approach to understanding the maritime development of the Atlantic world. Consequently, the maritime archaeology conducted in the Atlantic consists of a mix of scholarship focusing on many diverse geographical and temporal areas. This is no doubt influenced by the vast size that the Atlantic covers. Its waters flow across two hemispheres and connect four continents; from prehistory to the present, many cultures have utilized Atlantic waters for subsistence, transportation, trade, and warfare. Despite the lack of a unified approach, however, the maritime archaeology of the Atlantic can be seen as contributing to scholarly understanding of several significant research areas. Key research themes that maritime archaeologists have addressed using Atlantic sites include the study of ships of exploration, the impact of global commerce and warfare during the past 500 years, and the protection of underwater cultural heritage from treasure hunting. In recent years, Atlantic sites have also been used to examine significant emerging perspectives such as deepwater archaeology, prehistoric underwater archaeology, and maritime cultural landscapes.

Key Issues and Current Debates

Shipwrecks from the Age of Exploration

The Spanish and Portuguese were leaders in the field of global exploration, and shipwrecks from the Atlantic have contributed greatly to the understanding of early Iberian global seafaring. The earliest known European shipwreck site in the New World is the Molasses Reef wreck from the Turks & Caicos Islands, which sank in the early 1500s. This wreck and the slightly later Highborn Cay shipwreck from the Bahamas are typically included in discussions of Caribbean sites, but both actually lie in the Atlantic Basin. Because of their early dates, the Molasses Reef and Highborn Cay shipwrecks are significant finds, but in both cases, archaeologists did not arrive on the scene until after the sites had been damaged by treasure hunters (a pervasive problem in Atlantic maritime archaeology that will be discussed in greater detail later in this entry). Formal archaeological work at the Molasses Reef site began in 1982 under an Institute of Nautical Archaeology (INA) team led by Donald Keith (Keith et al. 1984). Excavations conducted from 1982 to 1986 revealed that the vessel was armed with at least 18 swivel guns and personal weapons such as crossbows, *arquebuses* (shoulder-fired guns), *harquebuts* (hand cannons), and cast iron grenades. A pair of *bombardetas* were aboard, but were not fitted for use at the time of sinking (Keith 1988: 60–63). Additional artillery included one *cerbatana*, a carriage-mounted gun. Items of ship's equipment from the site include one anchor, an axe head, a lead-sounding weight, and a possible pump valve. Ceramic sherds from olive jars, storage pots, bowls, and basins were also present. As a whole, the ordnance and artifact assemblage

suggests a Spanish origin for the vessel. Alternatively, analysis has shown that much of the ballast came from Lisbon, Portugal, so the ship may have been Portuguese instead (Lamb 1988). Unfortunately, only about 2% of the ship's hull remained; extant timbers suggest a vessel about 20 m long and 5–6 m in beam (Oertling 1989a).

The Highborn Cay wreck (Keith 1988: 59–60; Oertling 1989b; Smith et al. 1985) was discovered by divers in 1965 and subjected to salvage in the late 1960s. Archaeologists became interested in the site in the 1980s, after noting similarities between the artifacts from this site and those from the Molasses Reef wreck. Excavations were begun in 1986 and soon revealed a vessel similar in size to the Molasses Reef vessel, but with much better hull preservation. Fragments of the ship's backbone, including the keel, stem, and keelson, which included a mast step, were preserved. Other surviving timbers included frames, outer hull planking, ceiling (interior) planking, and footwales (longitudinal timbers on the interior that provide strength at the turn of the bilge). The ship was armed with at least 2 *bombardetas* and 13 swivel guns. Few ceramics were found; these include sherds from a bowl and a small pitcher. Likewise, only one personal artifact, a knife handle, was discovered. The paucity of personal artifacts and the fact that two of the three anchors discovered at the site seem to have been deployed at the time of sinking have led to the interpretation that the ship sank at anchor and that the crew had sufficient time to take their possessions with them when they abandoned the vessel. It seems possible, however, that some personal possessions may have been removed by salvors before archaeological excavations began.

The site of Red Bay, Labrador, Canada, provides some of the best evidence for early Iberian contact with the New World (Grenier et al. 2007). In the sixteenth century, Red Bay was utilized by Basque seafarers pursuing whales. The Basque had a whaling tradition that dates back to at least the twelfth century, but by the early modern period, stocks of whales off the European coast had been heavily depleted. With the discovery of the New World, intrepid Basque sailors soon began exploiting whales on the far shore of the Atlantic. From July through October, pods of right whales migrate through the Straits of Belle Isle. Red Bay, located close by, provided an ideal anchorage for fleets hunting these whales. Archaeological excavations on the shores of Red Bay in 1977 first provided evidence for tryworks used to render whale oil, while archival research in Spain revealed that several whaling vessels had been lost in the bay. Following the clues provided by the archives, in 1978 archaeologists discovered the remains of one such vessel, believed to be the galleon *San Juan*, which sank in 1565. Subsequent archaeological fieldwork has revealed three other galleons, along with the remnants of whaleboats. The Red Bay site complex is particularly significant for the details that it provides about life aboard whaling ships and rendering operations ashore, as well as for the information provided about Iberian ship construction, as the cold waters preserved the hulls to a greater extent than is commonly found on wrecks from lower latitudes. The Red Bay archaeological project is also noteworthy for its methodology. The hull of *San Juan* was excavated, dismantled, brought ashore, and recorded in great detail, then reburied on the bottom. Returning the timbers to the seabed obviated the need for costly, long-term conservation of the hull remains yet provided for their protection.

Another significant early Iberian vessel is the Western Ledge Reef wreck from Bermuda (Watts 1993). This shipwreck, which dates to about 1600, was discovered in 1964 and salvaged periodically until the late 1980s. From 1988 to 1991, East Carolina University and the Bermuda Maritime Museum recorded and excavated the site. Artifacts include cannon, versos, a bronze bell, navigational dividers, and sherds from olive jars, pitchers, and colono ware. The latter, along with bones from a white-tailed deer, indicate that the Western Ledge vessel had probably been to North America and was likely returning to Europe when it struck Bermuda's reef. The artifacts indicate that the ship was probably Spanish. A significant portion of the hull, including parts of the keel, keelson with mast step, sternpost, stern knee, frames, outer hull planking, ceiling planking, and transom planking, was preserved. The hull remains were

deemed significant enough to raise and conserve; at the time of this writing, the hull timbers are undergoing analysis and reconstruction.

The Azores Islands served as a critical waymark for Iberian vessels returning to Europe from both the New World and the East Indies. In the 1990s, archaeologists began a program to document and preserve the Azores' maritime heritage. A key focus of this program has been Iberian ships from the Age of Exploration. Investigations at Angra Bay, Terceira Island, revealed several shipwrecks. One of these, designated Angra D, represents the substantially preserved hull of a large Iberian vessel from about 1600 (Garcia and Monteiro 2001). The ship was probably close to 40 m in length, with a beam of about 8 m, and displaced approximately 700–800 t. Surviving timbers include the entire keel and keelson, the sternpost assembly, the main mast step, nine riders, numerous frames, outer hull planking, footwales, ceiling planking, and stanchions. The vessel lay on one side, with the result that parts of deck beams, which are often not preserved, were buried by overburden and thus survived. Rope and a double block provide evidence for the rigging; other artifacts provide abundant testimony to shipboard life. These include wicker baskets and barrel staves, combs, a religious figurine, a thimble, and pins. Chinese porcelain compliments the ubiquitous olive jars in the ship's ceramic assemblage. Bones from cow, chicken, and fish, along with almonds, raisins, and corn, testify to the crew's diet.

Although extent of hull preservation varies widely among the Iberian wrecks from the Atlantic Ocean, these, taken in concert with other Iberian vessel finds from the Caribbean, Gulf of Mexico, Great Britain, and continental Europe, have revealed enough about construction details to allow Oertling (2005) to postulate an "Atlantic tradition" vessel type. This consists of a package of 11 constructional features that seem common to fifteenth- and sixteenth-century Iberian vessels. Significant among these are the use of dovetailed mortise and tenon joints at the intersection of floors and first futtocks, a feature that provides the most readily identifiable indication that a wreck is Iberian. Another feature that can be used to readily identify Iberian vessels is a mast step formed from an enlarged section of the keelson and supported by lateral buttresses on either side. Iberian-Atlantic tradition vessels also feature preassembled central frames (the number varies based on the size of the ship) that indicate that Iberian naval architects were able to plan the shape of the central part of the hull before construction (Castro 2007), a significant advance over earlier European shipbuilding methods. Other significant features of this tradition include Y-shaped frames at the stern and keelsons notched to fit over the tops of the floor timbers.

A significant question concerning Iberian shipbuilding is whether or not archaeological sites can be used to identify particular types of vessels known from historical records. Atlantic sites such as Red Bay have proved critical in identifying galleons, as there is a good deal of certainty that the wrecks discovered there are those of historically known vessels such as the *San Juan*. Other types remain elusive. The caravel was one of the most important Age of Exploration ships; these small vessels were ideal for exploring unknown waters. Two of Columbus' vessels, *Nina* and *Pinta*, were caravels, and Vasco de Gama also employed them in his successful voyage to India. The evidence indicates that Iberian vessels shared the majority of their constructional details in common, despite size, so it does not seem possible to identify caravels on the basis of construction. Based on size, however, three of the Atlantic wrecks, the Molasses Reef, Highborn Cay, and Western Ledge Reef shipwrecks, offer tantalizing candidates for caravels. Future research may be able to solve this puzzle.

While Iberian vessels dominate the Age of Exploration shipwrecks investigated in the Atlantic, one significant early English site has also been excavated. This is the remains of the *Sea Venture*, which wrecked in Bermuda in the summer of 1609 while en route to the Jamestown colony (Wingood 1982; Adams 1985). Very little is known about early seventeenth-century English ship construction, and *Sea Venture*'s hull provides much needed archaeological evidence. About 15.5 m of the keel survived, with additional evidence to indicate that it was originally

approximately 22 m long. At its forward end, part of the keel to stem scarf remains. The size of keel indicates that *Sea Venture* was probably originally around 30 m long on deck, which agrees well with historical records that state that the ship was of 100 t. Fragments of eighteen frames, including floor timbers and futtocks, survive. Remains of deadwood, outer hull planking, ceiling planking, and sleepers (like footwales, these were longitudinal timbers that provided support at the turn of the bilge) were also recorded. In addition to the information it provides about seventeenth-century English ship construction, the *Sea Venture* excavation is also notable for the careful attention to stratigraphy (Adams 1985: 279–284), something not seen on many underwater excavations.

Global Commerce and Warfare

The Age of Exploration laid the groundwork for European expansion. Over the past five centuries, European colonization and commerce, along with their attendant warfare, shaped the world in which we live today. It is no exaggeration to say that today's globalization is merely the most recent aspect of a phenomenon that began 500 years ago. During that time, the Atlantic Ocean has served as a key highway for European expansion, and maritime archaeologists have investigated numerous sites that provide evidence for this.

The Spanish and Portuguese were leaders in the Age of Exploration, a key goal of which was the growth of commerce. In the seventeenth century, Portuguese merchant vessels transited the Atlantic on their way to bring back the wealth of the East Indies. The wreck of one such vessel has been investigated in detail by archaeologists. This vessel, the nau *Nossa Senhora dos Mártires*, sank at the mouth of the Tagus River, Portugal, in September 1606 on its return voyage from India (Castro 2003, 2005). The ship was carrying a cargo of peppercorns, many of which were salvaged soon after it sank, along with much of the ship's armament, fittings, and stores. The site was subjected to further damage in the 1980s, when sport divers looted the wreck. Archaeological excavations from 1996 to 1997, however, revealed that much valuable information remained. The presence of a large quantity of peppercorns provided evidence for the wreck's identity and its cargo. The ship's equipment, including three astrolabes, dividers, and sounding leads, were also recovered. Asian pottery in the form of Chinese, Burmese, and Japanese ceramics hints at the details on cross-cultural contacts that shipwrecks such as this can offer. The Pepper Wreck is also valuable for the data that it provides about seventeenth-century Portuguese ship construction and design. Analysis of the surviving hull structure, which includes a portion of the bottom forward of amidships, combined with historical shipbuilding treatises and iconography, allowed Castro to create a reconstruction of the ship's original shape and dimensions. Further research will include the construction of models to test hull strength and hydrodynamic properties (Castro and Fonseca 2006). Recently, another possible Portuguese East Indiaman has been investigated at Oranjemund, Namibia. This site is located in a high-energy environment just offshore. Investigations in 2008 revealed portions of the ship's hull and tin, lead, and copper ingots. Numerous personal artifacts were also found. Coins from the wreck suggest that the ship sank shortly after 1525; based on this, the vessel has been tentatively identified as the Indiaman *Bom Jesus*, lost on its outbound voyage in 1533 (Werz 2010). Additional research is planned for the near future.

The Oranjemund Shipwreck highlights the potential that the southern Atlantic coast of Africa holds for examining European merchant vessels lost while voyaging to or returning from Asia. In addition to Portuguese vessels, Dutch East Indiamen regularly followed a similar route around the Cape of Good Hope. One of the first VOC ships to be investigated in South African waters was the *Meresteyn*, lost in 1702 at Saldanha Bay, north of Cape Town. Unfortunately for archaeology, the site was looted following its discovery in 1971. Archaeologists did, however, have the opportunity to record some artifacts before they were auctioned (Marsden 1976). These consist primarily of small arms equipment and personal possessions which, lacking context, provide little in the way of data regarding life aboard the ship. Cases such as the looting of the

Meresteyn helped increase public awareness of the need to protect historic shipwrecks in South Africa. When sport divers discovered two other VOC shipwrecks, those of the *Oosterland* and *Waddinxveen*, at Table Bay in the 1980s, they reported them to the appropriate authorities. As a result, archaeologists had the opportunity to examine these ships, which were sunk in a storm in May 1697 while on their return voyage to Europe. To date, scholarly research has included interdisciplinary investigations by archaeologists, oceanographers, geologists, botanists, and other specialists (Werz 2009).

One of the best VOC shipwreck sites in Atlantic waters is that of the *Mauritius*, which sank in the Gulf of Guinea on its return voyage in 1609 (L'Hour et al. 1990). The wreck was discovered in 1985 and excavated in 1986. Excavations revealed that a section of the hull, approximately 15 m × 6 m, survived. Extant structure includes portions of the keel, 24 floors, 22 first futtocks, outer hull planking, ceiling planking, and pine sheathing that once protected the outer hull. Evidence for timbers that have now vanished is preserved as well; for example, bolts protruding into the interior at the floor – first futtock overlap – show that the ship originally had footwales to provide extra strength at the turn of the bilge. *Mauritius*' hull is significant because it provides an example of a double-planked East Indiaman. The inner layer of hull planking was treenailed to the frames, while the outer layer was fastened to the inner with nails. Lead sheathing was sandwiched between the two layers of planking. About 122 t of zinc ingots, peppercorns, and Chinese porcelain provide evidence for the types of cargo transported back to Europe aboard a returning Indiaman.

At least seven VOC wrecks have been identified in British waters; of these, five can be considered to be Atlantic sites. The Dutch East Indiamen *Lastdrager* (1653), *Kennemerland* (1664), and *De Liefde* (1711) were all lost in the Shetland Islands. The bow section of *Lastdrager* was salvaged in the 1970s and some 3,000 artifacts recovered (Stenuit 1974), but unfortunately, these were sold at auction and so lost to scholarly examination. The *Kennemerland* site was the subject of a long-term study by the noted British maritime archaeologist Keith Muckelroy (Muckelroy 1978). Muckelroy's analyses focused on determining the types of information that could be contained within highly scattered wreck sites, along with developing methodologies for the best ways to study such sites. Muckelroy also utilized the *Kennemerland* site in a seminal examination of formation processes at underwater sites. Like *Kennemerland*, *De Liefde* represents a scattered wreck site. Excavations in the 1960s, however, revealed a highly varied collection of artifacts, including gold, silver, and copper coins, small arms, ceramics, utensils, and personal items (Bax and Martin 1974). The wreck of the VOC ship *Adelaar*, which sank in the Outer Hebrides Islands in 1728, has also been investigated (Martin 2005). Like the wrecks in the Shetlands, the *Adelaar* site was highly scattered due to the dynamic nature of the wreck site. As at the *Kennemerland* site, however, investigations revealed that meaningful archaeological patterns were still present. These sites have helped to counter the argument advanced by treasure hunters that shipwrecks located in dynamic environments cannot provide useful archaeological data and thus should be allowed to be salvaged. A final VOC shipwreck in British Atlantic waters, the *Hollandia*, wrecked in the Isles of Scilly in 1743. The site was located in 1971 and subsequent excavations undertaken (Cowan et al. 1975). *Hollandia* was outward bound when it went down, and the finds from the wreck include over 35,000 silver coins. Marsden (1978) has discussed the significance of the finds of coinage from outward-bound VOC ships such as *Hollandia*, *De Liefde*, and *Amsterdam* (which wrecked near Hastings in 1749). Far from being merely treasure, the coins from the sites such as these provide evidence for a key economic system in eighteenth-century Europe. The Dutch East India Company paid for Asian goods with coinage that they had to secure in turn primarily from Spanish sources in the New World. Marsden shows that further study of VOC shipwrecks is needed in order to illuminate the complex economic interactions that enabled this system to work. Marsden's study offers strong evidence for the

need to examine coinage from shipwreck sites archaeologically rather than viewing it simply for its monetary value.

Atlantic global commerce included not only goods but also the unfortunate transportation of human cargoes. It is estimated that more than ten million Africans were forcibly transported across the Atlantic and sold into slavery in the New World. Maritime archaeologists have yet to investigate this trade to the same degree as historians. One site that is currently undergoing study is the slave ship *Trouvadore*, which wrecked in 1841 off East Caicos in the Turks and Caicos Islands (Leshikar-Denton 2010a: 638). When it sank, *Trouvadore* was carrying nearly 200 African slaves; the majority of these landed safely on the Turks and Caicos Islands, where many descendants live to this day. The *Trouvadore* site was discovered in 2004 and has been investigated by Ships of Discovery and the Turks & Caicos National Museum. Site interpretation involves working with the local islanders to investigate, interpret, and present a site that may provide key for shedding light on a dark chapter in maritime history.

European expansion was accompanied by naval warfare, as nations sought to build empires, protect trade, and threaten the commerce of rivals. Maritime scholars have examined the archaeology of Atlantic naval warfare at numerous sites. Wrecks from the 1588 Spanish Armada (Martin and Parker 1999) have revealed how the Spanish fleet suffered from a variety of problems, such as inferior cannon that were not well-suited to warfare at sea. Other significant Atlantic naval sites investigated through maritime archaeology include the British frigate *Dartmouth* (Adams 1974), HMS *Maidstone* (de Maisonneuve 1992), and the CSS *Alabama* (Watts 2007). To date, most studies of warships have been site specific and concerned largely with examining famous vessels. Sites such as the Spanish vessel *Salvador*, however, which was lost off the coast of Uruguay in 1812 while transporting troops to quell a revolt (Nasti 2001), highlight the potential that maritime archaeology has for addressing issues such as colonialism, which has significance to the wider field of archaeology.

Treasure Hunting and Heritage Protection

While looting of archaeological sites on land remains a problem throughout the world, nowhere is this problem more apparent than on underwater sites. Since the beginning of the field, maritime archaeologists have waged a constant struggle with treasure hunters who seek to exploit underwater sites for commercial gain, on the one hand, and a public that often does not understand the distinction between legitimate archaeology and treasure salvage or the need to protect underwater archaeological sites on the other hand. While destruction of underwater sites by treasure hunting is a worldwide problem, some of the key battles, and some of the most recent developments concerning the protection of underwater cultural resources, have occurred in the Atlantic. Many of the wrecks discussed above were looted before archaeologists arrived on the scene. In other cases, treasure salvors have been granted legal access to shipwrecks, and thus the exploitation and dispersal of these sites has occurred perfectly legally. One such case from the Atlantic Ocean is the pirate vessel *Whydah*, which sank off Cape Cod, Massachusetts, in 1717. Despite the attempts of authorities to provide for proper archaeological procedures, the *Whydah* episode resulted in a debacle, as archaeologists were not able to perform their duties to satisfactory standards (Elia 1992).

The problem of treasure hunting has been complicated by the difficulty in finding a legal framework to protect underwater archaeological sites. The 1982 Law of the Sea Convention specifies that coastal states have control over cultural resources located in their Territorial Seas (up to 12 nautical miles from the coast) and Contiguous Zones (up to 24 nautical miles). Beyond this, coastal states may claim rights to an Exclusive Economic Zone that extends out to 200 nautical miles; some nations have also claimed rights out to the limits of the continental shelf. In these areas, however, the Law of the Sea provides no explicit protection for cultural resources. Thus, any archaeological sites beyond 24 nm have no legal protection under the Law of the Sea and can be exploited by anyone with the capability to do so. Technological developments in deep sea

exploration have made these deepwater sites ever more accessible to treasure hunters. In 1987, for example, the Columbus-America Discovery Group led by Tommy Thompson discovered the wreck of the steamship *Central America*, which lay some 200 miles off the coast of South Carolina in approximately 2,400 m (8,000 ft) of water (Kinder 2009). ROVs were used to locate and subsequently salvage the wreck, which went down in a storm in 1857 while carrying 21 t of gold. Salvage efforts recovered an estimated $100–150 million in gold, along with myriad other artifacts. Although the salvagers specifically stated that scientific knowledge was one of the goals of the project, this has yet to materialize; instead, the recovered gold is offered for sale. A similar story comes from another Atlantic shipwreck, the steamer *Republic*, which sank about 100 miles off the coast of Georgia in 1865 with a cargo of gold and silver coins (Vesilind 2005). The wreck was discovered in 2003 by US-based Odyssey Marine Exploration, Inc., who salvaged an estimated $75 million in coinage from the site. Like the *Central America* salvors, Odyssey claims to be conducting archaeological research, but it is clear that commercial exploitation remains the company's chief goal; Odyssey offers *Republic* artifacts, including coins, bottles, and chunks of coal, for sale on its website. Whether or not such groups record and publish sites to archaeological standards, the commercial nature of these enterprises contradicts the ethical principles of archaeological bodies such as the Society for Historical Archaeology (SHA) and Society for American Archaeology (SAA).

Projects such as the *Central America* and *Republic* have been allowed to occur because, until recently, there was no legal framework for preventing the exploitation of underwater sites located beneath the high seas. This bleak picture for the future of Atlantic maritime archaeology, however, has been lessened somewhat in recent years by the adoption of the 2001 UNESCO Convention on the Protection of the Underwater Cultural Heritage (Leshikar-Denton 2010b). The Convention entered into force in January 2009, when 20 nations had signed it. To date, 40 nations, including 16 that border the Atlantic, have signed the Convention. The 2001 Convention provides standards for the protection of underwater cultural heritage, defined as "all traces of human existence having a cultural, historical, or archaeological character which have been partially or totally underwater, periodically or continuously, for at least 100 years." Unlike the Law of the Sea Convention, the 2001 UNESCO Convention thus embraces the protection of all underwater sites, regardless of geographical location. It remains to be seen how well the Convention can be enforced on the high seas, but the agreement is a definite step forward in cooperation between nations to protect submerged cultural resources. The Convention also contains standards for the proper study of underwater resources; these include properly trained maritime archaeologists, a preference for in situ preservation and noninvasive methodologies, and a prohibition against exploiting underwater sites for commercial gain. Some notable maritime nations, such as the United States and the United Kingdom, are not signatories, but in the case of the former, government cultural resources managers are finding ways to implement the Convention's rules into their policies (Varmer et al. 2010).

Another way to protect underwater cultural heritage is by designating special geographical areas as protected zones. The United States' National Marine Sanctuaries Act provides a model for such legislation. The NMSA provides for the protection of natural and cultural resources in certain designated areas. At each sanctuary, officials are responsible for inventorying and managing shipwrecks and other submerged cultural resources located within the bounds of each sanctuary. The first sanctuary officially designated under the NMSA was the USS *Monitor* National Marine Sanctuary, designated to protect the site of that Civil War ironclad shipwreck off the coast of North Carolina in 1975. Two others, Gray's Reef National Marine Sanctuary (1981) and Stellwagen Bank National Marine Sanctuary (1992), have been created off the US Atlantic seaboard. The NMS program represents a highly effective strategy for preserving maritime heritage for future generations.

Future Directions

Maritime archaeological work in the Atlantic Ocean to date has been primarily focused on the topics discussed above, but as the field of maritime archaeology evolves, new perspectives continually emerge.

Deepwater Archaeology

Given the amount of maritime traffic throughout history, deepwater fieldwork will no doubt become an important part of future maritime archaeological work in the Atlantic. The discovery of the world's most famous shipwreck, the RMS *Titanic*, in 1985 at a depth of 3,800 m (c. 12,500 ft) sparked worldwide interest but has resulted in little archaeological work to date. As the wreck lies in international waters, rights to the wreck were granted to RMS Titanic Inc., which has subsequently conducted salvage operations at the site. According to the company's website (rmstitanic.net), more than 5,000 artifacts have been raised. This work, along with that of other salvage companies, has resulted in damage to parts of the site and the removal of artifacts without proper archaeological recording and with little regard for site preservation issues. Pleas by archaeologists finally resulted in collaboration between RMS Titanic, the Institute of Nautical Archaeology (INA), the National Oceanic and Atmospheric Administration office of National Marine Sanctuaries, the National Park Service's Submerged Resources Center, Woods Hole Oceanographic Institute, and other groups (Delgado 2010). Under the archaeological direction of maritime archaeologist James Delgado, RMS Titanic mounted an expedition in 2010 to map the *Titanic* site using sonar and 3D optical imagery. This information will be used to develop the first archaeological plan of the entire wreck site.

Issues raised by the *Titanic* experience – site access, resource sustainability, and site management – will apply to other deepwater archaeology projects in the Atlantic for years to come. Already, other famous shipwreck sites, such as the World War II German battleship *Bismarck* and HMS *Hood*, have been located, and more discoveries are sure to follow. Maritime archaeologists have not yet reached a consensus regarding how best to conduct deepwater research. Treasure salvors argue that such research cannot be performed by archaeologists because of the skills, expenses, and equipment involved and have thus pushed for collaboration between commercial salvage companies and archaeologists. These claims have been elegantly countered, however, by maritime archaeologist Jonathan Adams (2007), who notes that cooperation is incompatible because archaeologists are bound by ethical standards not to exploit artifacts for commercial gain and because archaeologists do indeed have the potential to carry out deepwater projects. Adams cites successful deepwater archaeological work in the Mediterranean and Black Seas in support of his arguments and urges archaeologists to integrate future deepwater research into the types of international research and management plans advocated by the 2001 UNESCO Convention. This seems the most sensible course. A key goal for deepwater research in the Atlantic is for maritime archaeologists to convince the public, who often do not understand the differences between treasure hunters and archaeologists, that deepwater shipwrecks represent finite resources that should be managed for the benefit of all rather than being exploited for the profit of a few.

Prehistoric Underwater Archaeology

In recent decades archaeologists have come to realize that much valuable data concerning prehistoric habitation sites and the spread of humans around the globe lies under water. Eustatic sea level rise at the end of the Pleistocene resulted in the inundation of many prehistoric coastal sites, which now lie submerged on the continental shelves. Until recently, most interest in submerged prehistoric sites has come from prehistoric terrestrial archaeologists. Maritime archaeologists, with their specialized knowledge in underwater archaeological methodology and access to high-tech underwater surveying equipment, however, have the potential to make significant contributions to the study of submerged prehistoric settlements and coastal migration routes. To date, most such research in the Atlantic has been conducted off the

coasts of North America and Europe (Benjamin et al. 2011; Gusick and Faught 2011). Such research typically has two main thrusts: (1) the reconstruction of submerged paleolandscapes and (2) the identification of paleoshorelines. A primary goal is to develop predictive models for locating submerged prehistoric sites, which can then be studied using underwater archaeological techniques. Because of the nature of this work, research into submerged prehistoric landscapes typically involves interdisciplinary collaboration between maritime archaeologists and other specialists such as geoarchaeologists, marine scientists, and geologists. In the coming years, research into this area should help refine scholarly understanding of issues such as the peopling of the Americas.

Maritime Cultural Landscapes

The last two decades of maritime archaeology have witnessed a surge of interest in the "maritime cultural landscape" approach, an idea promulgated by Swedish maritime archaeologist Christer Westerdahl (1992). The maritime cultural landscape approach advocates studying shipwrecks as part of the cultural systems that produced them rather than as isolated sites. Such an approach is well-suited to future work in the Atlantic basin, which consists of a mosaic of diverse, overlapping, interconnected systems. Several recent projects in the Atlantic serve as guideposts for future work in looking beyond shipwrecks to wider cultural processes. One innovative study utilized data from the sloop of war HMS *Swift*, lost off the coast of Patagonia, Argentina, in 1770, to examine British actions in a colonial context (Dellino-Musgrave 2006). The study used artifacts excavated from the wreck site, primarily pottery, to illuminate the ways that material culture was used to express status relations and maintain a sense of "Britishness" in a colonial setting. Archaeologist Richard Gould, long a proponent of using shipwrecks to examine cultural processes, has interpreted the wreck of the nineteenth-century barque *North Carolina* as a possible crime scene (Gould 2005). *North Carolina* went aground on Bermuda under suspicious circumstances on January 1, 1880. Archaeological fieldwork revealed discrepancies between the material culture evidence and historical accounts of the sinking. Gould concludes that these may represent evidence that the vessel was deliberately wrecked, possibly with the intent to collect insurance money. A final recent project that takes maritime archaeological interpretation beyond the site is the study of the *H.L. Hunley* and USS *Housatonic* naval battlefield (Conlin and Russell 2006). In 1864, *Hunley* sank *Housatonic* in the Atlantic Ocean just off Charleston, South Carolina, becoming the first submarine to sink an enemy vessel in combat. Unfortunately for the crew of the *Hunley*, the submarine sank soon after fatally damaging the union warship. Following its discovery in 1995, the *Hunley* was raised; as part of the overall research project, the *Housatonic* and surrounding area have been examined as well. Maritime archaeologists utilized methodology adapted from that pioneered by historical archaeologists on battlefield sites such as the Little Bighorn. This approach views the entire site as a landscape, the features and artifacts of which can reveal information regarding the progress of the battle. In this case, the battlefield survey helped provide a greater understanding of the engagement between *Hunley* and *Housatonic* than that provided solely by historical accounts.

Atlantic World: Historical Archaeology

Liza Gijanto
St. Mary's College of Maryland, St. Mary's City, MD, USA

Introduction

Archaeologists have only recently begun to identify their research as part of Atlantic studies (see Kelso 2010) despite the Atlantic World being a central focus of the subfield of historical archaeology since its inception. This being the case, the research carried out by archaeologists of the Atlantic World has been, and continues to be, categorized under a number of studies falling within several discrete subfields, such as colonial, indigenous, contact era, African Diaspora, New World, and a host of other "archaeologies," within the larger field of historical archaeology in the Americas, parts of Western Europe, and West and Southern Africa. Because a specific "Archaeology of the Atlantic World" was not a distinct research focus in the early years of historical archaeology, nor has it emerged as a discrete area of study despite a growing interest, defining it now requires an examination of a number of disparate research agendas.

The earliest explorations of "historic" sites as part of the new historical archaeology emerging in the 1950s were conducted at sites such as Jamestown and Williamsburg, known and memorialized for their strong associations with the founding of the United States as well as European expansion and settlement in the New World, and not as part of a broader agenda to examine the Atlantic World. Those archaeologists that did use the term "Atlantic World" in describing their work sought to designate a specific time frame within the larger field of historical archaeology, rather than a particular subject matter or research agenda. As the field of historical archaeology was developing, emphasis was placed on defining this historical period, characterized by both European contact and settlement of the Americas, beginning at the end of the fifteenth century, with the voyages of Columbus, and extending into the present. It can be argued that much of historical archaeology was, and remains, largely Atlantic World archaeology, and this is primarily due to the subject's early thematic focus and its strong emphasis on trans-Atlantic interactions. This is not only seen in both early and current research at Jamestown and Williamsburg but in some of the earliest investigations in the Caribbean as well (see Deagan in Kelso 2010). Just as the discipline of historical archaeology had trouble defining its subject in the early days, those explicitly studying the Atlantic World have had similar difficulties including the denotation of discrete regional and

temporal boundaries, although these debates have largely been the domain of historians (Bailyn 2005).

Definition

An immediate predecessor of the industrial age, the Atlantic era is concurrently referred to as the "postmedieval," "early modern," and "capitalist world" by historical archaeologists depending on their own national background and training. A single, explicit definition of what the Atlantic World was is not possible, largely as a result of the number of areas and powers involved in trans-Atlantic commerce over the course of roughly four centuries. While there is no single, all-encompassing definition of the scope, size, and period of the Atlantic World, those studies attempting to define a general framework have largely fallen under the purview of historians (Bailyn 2005). Most historians of Atlantic history agree that "during a significant chunk of time, extending at least from 1500 through 1800, the Atlantic World—which is to say, Western Europe, the Americas, and West Africa—was sufficiently integrated. . ." (Coclanis 2007: 113), thus requiring an integrative research agenda that highlights the connections, responses, and consequences of this integration in a unitary fashion. Following this definition, in the broadest sense, the period of the Atlantic World begins in the mid-fifteenth century with European exploration in West Africa and ends sometime in the mid- to late nineteenth century with the advent of the industrial age in Europe, in addition to the period of abolition of slavery in the Americas. As a historical concept, the term "Atlantic World," therefore, refers to those regions with a shore on the Atlantic Ocean and their historical interconnectedness or integration, through maritime exchange that brought about cultural encounters and in turn the mass movement of people between these areas. The latter was spearheaded by European efforts at commerce and colonization, initially in Africa and later in the Americas, including the early period of indentured servitude in the Caribbean and Chesapeake, for example, followed by the era of the trans-Atlantic slave trade throughout the Atlantic sphere. Colonization as part of the early Atlantic is also considered in Ireland.

In the most basic geographical sense, the Atlantic World comprises all coastal regions of Europe, Africa, and the Americas physically connected by the Atlantic Ocean. Additionally, the areas of the Americas and Africa that are often included in studies of the Atlantic World by researchers may include associated interior regions but are limited by historical incorporation into various European colonial ventures. Attempts to restrict the geographical and temporal boundaries of this period are further complicated by the various stages of Atlantic development tied to the dominance of successive European powers throughout its existence. The initial period begins with Portuguese ventures in West Africa culminating with their rivalry with the Spanish in South America. Immediately on their heels were the Dutch, English, and French as well as an array of smaller players, such as the Danes, all seeking their own territories in Africa and the Caribbean, as well as in continental North and South America. Thus, within the Atlantic World, researchers have highlighted a series of smaller "Atlantics" tied to European nationalistic ventures culminating in colonial boundaries. This is most aggressively seen in the English-French rivalry in the Caribbean and West Africa.

Historical Background

Historical archaeology of the Atlantic World began with historic sites archaeology in the United States in the mid-twentieth century. Drawing on the earlier definitions of J. C. Harrington and Bernard Fontana, who were among the pioneers in this field, Robert Schuyler (1970: 84) later defined the field's focus as "the expansion of European culture into the non-European world starting in the fifteenth century and ending with either, industrialization or the present, depending on local conditions." Some of the first historical sites investigated in the United States were in Virginia, for example, Jamestown, and represented some of the earliest moments of

English commercial expansion. Even though Schuyler (1970: 85) states that the field's subject matter may begin as early as 1415, with the "Portuguese penetration of Africa," he addresses the fluid nature of this period noting that the regions subject to European expansion geographically "fluctuated from decade to decade" and the fact that the bulk of the initial studies classified as historic sites archaeology were carried out in the United States and more particularly the southeast (e.g., the work of Ivor Noël Hume in Virginia). Hence, as a field, historical archaeology began with an emphasis on European exploration in the New World demonstrating a distinctly Americanist perspective (Gilchrist 2005). These early projects highlighted the United States' beginnings and the experience of settlers and colonists in a foreign land yet specifically addressed their successes, failures, and resourcefulness in creating the larger Atlantic World.

This early perspective led to an emphasis on the English Atlantic sphere, while little attention was given to other European groups or indigenous communities (Deagan 1982: 161–162). Another definition addressing historical archaeology's focus in the Atlantic World era was presented by James Deetz. While Americanist in perspective, this definition is slightly less Eurocentric in nature. In it the author describes the field as "the archaeology of the spread of European cultures throughout the world since the fifteenth century, and its impact on the indigenous people" (Deetz 1977: 5). In the revised text, Deetz (1996: 5 emphasis added) altered the latter half of this statement to read "and *their* impact on *and interaction with the cultures of indigenous peoples*." This amended statement recognizes that both "European" and "indigenous" people are not monolithic entities, and as such, there were multiple experiences of contact and interaction throughout the Atlantic era. Additionally, it reflects a growing trend within historical archaeology to define a more global subject matter, thus opening a dialogue between archaeologists in the Americas, Europe, and parts of Africa (e.g., Falk 1991).

The emergence of historical archaeology in Europe postdates studies in the United States, even though the subject matter roughly corresponds with the era of the Atlantic trade, including its regional focus in the United Kingdom. Its designation as "Post Medieval" has had a tendency to marginalize its practitioners from the larger debates within global historical archaeology (Gilchrist 2005: 330), resulting in the gradual integration of the two perspectives. Attempts have been made to unite the field around investigations that largely fall within Atlantic studies (e.g., Egan and Michael 1999; Horning and Brannon 2009). Here again, the experience of the European has been the primary focus of study, as well as the impact and introduction of new commodities from the Americas and West Africa on European society.

Key Issues and Current Debates

Research within historical archaeology has moved from the sites of major events and influential men, like the homes of Thomas Jefferson, George Washington, and James Madison, to include the local or everyday lives of the invisible masses residing on these properties, as well as within urban spaces, examining topics of race, ethnicity, gender, and economic marginalization through multi-scalar perspectives. In fact, many of the debates that permeate historical archaeology as a whole are magnified within those focusing on the Atlantic era, notably those surrounding race or racialization (e.g., Orser 1996). This is also reflected in current research being carried out within Atlantic World studies as a whole. More specifically, there is an emerging emphasis on indigenous experiences and successes within the Atlantic. This is seen in studies of Native American communities when approached from an indigenous rather than a settler's perspective (Blanton and King 2004) and in investigations of indigenous trading communities in West Africa (DeCorse 2001).

Archaeologists have also followed the lead of Atlantic historians in defining the various "Atlantics" that coexisted. These are defined by a group of people sharing ethnic or national origins, a region, or a nation and its colonial or mercantile

empire. Likewise, the indigenous spheres of interaction are also receiving greater attention. The most explicit example of this is the recent attempt to construct a dialogue between historical archaeologists working on Atlantic period sites in Africa and contemporary African Diaspora sites in the Americas (Ogundiran and Falola 2007; Gijanto and Horlings 2010). Most importantly, archaeological investigations of Atlantic era sites in West Africa have significantly increased since the 1990s (e.g., DeCorse 2001; Monroe and Ogundiran 2012; Gijanto 2016). Other attempts at defining various Atlantics along nationalistic or imperial lines are less overt but nonetheless can be found in studies of the Irish (Orser 1996: 89–105; Horning in Kelso 2010) and, more recently, the Spanish and Portuguese (Funari and Senatore 2015), for example. Regional approaches that examine multiple people include those focusing on North America and South America, with a particular emphasis on Brazil as part of an Iberian Atlantic (e.g., Funari 2006; Deagan in Kelso 2010), or the Caribbean and its British and French regions (e.g., Kelly and Hardy 2011). In addition to terrestrial investigations, maritime archaeologists working within historical archaeology have investigated a number of Atlantic era sites in the United States (the *La Belle* by Texas A&M), the Caribbean (most famously Port Royal, Jamaica), and more recently in Africa including Ghana (The *Elmina* Wreck by Syracuse University) and South Africa (George Washington University's collaborative Southern African Slave Wrecks Project).

Beyond attempts to investigate regions or types of Atlantics, the approach taken by archaeologists considers a range of analytical models primarily aimed at understanding identity within specific socioeconomic spheres of interaction. This includes the work by Stephan Silliman (2009) on the northeastern Pequot in the United States, which presents a new perspective on the colonial experience through a postcolonial lens. This and other works investigate what it means to be "indigenous" and how this changes through the course of the Atlantic World era through interaction, trade, and at times subjugation. These issues are addressed by Silliman by utilizing theories of memory and highlighting the lived experience of everyday life by drawing on practice and agency theories.

International Perspectives

The large geographical expanse, involvement of multiple communities, and emphasized relationships between native and European communities have prompted historians and historical archaeologists to approach the Atlantic World in a variety of ways as discussed above. Though drawing primarily on geographical positioning, the connections formed between these regions through maritime travel, colonialism, immigration, and the slave trade manifested in strong political and cultural ties formed through commerce and exploration. The earliest archaeological excavations carried out as part of historical archaeology, or historic sites archaeology as it was originally named, were conducted at sites tied to discovery and early settlement by Europeans in the United States like Plymouth, Massachusetts, and Williamsburg, Virginia. In general, historical archaeology has been defined by its practitioners by its subject matter – namely, sites of European contact in the New World. While the former view of the Atlantic is consequently created from a New World perspective tied to mercantile conquest, in British archaeology this period falls under the umbrella of postmedieval studies including the development of the plantation system in Ireland in the seventeenth century (see Horning in Kelso 2010). In reaction to the restrictive nature of the Americanist-driven definition of the field, archaeologists have identified this period as a subject for historical archaeologists who employ concepts that are much more global in nature, such as the notions of the "Modern" (Johnson 1995) or "Capitalist" (Orser 1996) World. Both conceptions incorporate the period of the Atlantic World, though each extends the subject matter of the field into the late nineteenth and twentieth century. The emphasis on the spread of capitalism put forth in Matthew Johnson's (1995) and Charles Orser's (1996) formulations is in line with the idea of a modern world-system, originally formulated by

Immanuel Wallerstein (1974), that emerged as a result of European trans-Atlantic commerce. All of these research agendas have been criticized for their Eurocentric bias and particularly the emphasis they place on European experiences in, and their conquering of, the New World and parts of Western and Southern Africa. This includes the expansion of capitalism – deemed a European invention – and the decline of local polities in the Americas and in Africa. The recognition that maritime exploration did create the Atlantic, many argue, should not overshadow the experiences of local communities throughout the Americas and Africa in creating the Atlantic World. It is this point that historical archaeologists have been grappling with since they began to define the focus of their field.

To some extent, studies of culture contact and colonial encounters in the United States represent a move away from a focus on European settlement toward an understanding of the impact of this on indigenous populations. As Deetz indicates, this was a key topic of inquiry in historical archaeology, and many of the early studies argued for a loss of native culture. More recently, emphasis has shifted to include consideration of indigenous responses and reactions within colonial encounters in more active terms, through acts of resistance, cultural resilience, and hybridity. Furthermore, archaeologists from Europe, parts of Africa, the Caribbean, and Brazil in addition to the United States have begun to examine local interpretations of the capitalist system driving the Atlantic World. A prominent example of the shift away from the "European experience" within the United States is the subfield of African Diaspora archaeology which focuses on sites associated with populations of African descent in the Americas (and even some in Africa). African Diaspora archaeology's subject matter begins with the trans-Atlantic slave trade and continues into the twentieth century, yet the period that falls under the purview of the Atlantic World is usually considered to begin with the initial arrival of Africans in Maryland and Virginia in the seventeenth century and ends with the abolition of slavery in different areas of the Americas (see Fennell, Chan, Weik, Hauser, and Schávelzon in Ogundiran and Falola 2007). Outside of the United States, various Caribbean Islands have received equal attention with a particular emphasis on plantations and Maroon sites (see Haviser 1999) as well as spheres of African-European interaction in West and South Africa (see Monroe, Stahl, and Ogundiran in Ogundiran and Falola 2007; see Schrire in Falk 1991; DeCorse 2001).

Future Directions

Currently, Atlantic World archaeology is coming into its own. This is evidenced by the increase in sessions at the *Society for Historical Archaeology* annual meetings explicitly addressing the topic, such as the 2009 session "The French Fishery in Newfoundland: The Trans-atlantic Landscape of an Atlantic Borderland" or the 2010 session "The Chesapeake in the Atlantic World." Most recently, the 2012 meeting included sessions entitled "African Diaspora in Global Context," "Atlantic Connections and New Dimensions of Archaeology at Maryland's Birthplace," and "Conflict and Violence in the Making of the Atlantic World." These examples represent a shift from identifying the Atlantic as a temporal period to a more nuanced approach of connections and relationships between spaces and people. While the Atlantic World has been a topic of interest since the early days of historical archaeology, attempts to develop a pragmatic research agenda and to gather interested researchers for debate and discussion are still in the formative stages (e.g., Kelso 2010 drawing on the 2007 Society for Historical Archaeology Plenary session "Old World, New World, Culture in Transformation").

As seen in the titles listed above, archaeologists are focusing on the connections between regions and how these shaped local experiences in the Atlantic World. Many of these connections are being traced through the consumption of a single class of goods such as Barbara Heath's (2016) recent study examining the cowry shell trade including its use as currency providing a new interpretation of these objects at North American sites. Another tact being taken is the inclusion of studies of the Atlantic World within postcolonial archaeology, highlighting

indigenous experience and the legacy of globalization of colonialism.

What remains to be seen is if a single Atlantic World archaeology will emerge from these inquiries or if the field will remain dissipated within historical archaeology as a whole. What is clear, however, is that the growing interest in historical archaeology in the United Kingdom coupled with the increase of researchers focusing on Atlantic era sites in West Africa is driving the current rise in such investigations.

Atoll Archaeology in the Pacific

Frank R. Thomas
Oceania Centre for Arts, Culture & Pacific Studies, University of the South Pacific Laucala Campus, Suva, Fiji

Introduction

As islands formed by biogenic agents (unconsolidated carbonate sediments deposited by waves on reef platforms), atolls and table reefs, or low coral islands without lagoons, can be regarded as especially constraining habitats for human settlement. The challenges faced by people, both past and present, include low soil fertility, absence of perennial surface freshwater, and extreme vulnerability to flooding by storm surge and sea-level rise due to low elevation of the highly fragmented landmass, only a few meters above mean sea level. There are about 300 atolls and low coral islands in the Pacific and thousands of individual islets (*motu*). Several archipelagoes are dominated by these limestone islands, such as the Tuamotus, the Central and Eastern Carolines, the Marshall Islands, Kiribati, and Tuvalu.

Because of their small size, limited and at time fluctuating resources, and relative isolation, atolls are often perceived as marginal environments. While some human communities did not endure (Di Piazza and Pearthree 2001), a remarkable number were sustainable for centuries, taking advantage of opportunities many atolls provided and indicating a long history of resilience to environmental variability (Fitzpatrick et al. 2016). Despite these achievements, atolls have received relatively little coverage by Pacific archaeologists.

Definition

Derived from the Maldivian word, *atolu*, atolls are annular-shaped mid-ocean reefs surrounding a central lagoon, open to the sea in at least one place, which have formed on top of subsiding volcanoes, as theorized by Darwin and later confirmed by drilling. These reefs can be divided into several zones and associated marine habitats. Reef platforms that form atolls consist of reefs that reach sea level, notably along the windward margin. The seaward limit of the reef flat is demarcated by a reef crest, commonly an algal rim, and growing upwards of 1 m above low water mark in a high energy environment. Erosion of reef material results in the accumulation of unlithified or poorly consolidated sand or gravel that form *motu*, a Polynesian-derived word which some authors have equated with the term "islet" or dry land that may be isolated or near-continuous. Table reefs or reef islands are single coral islands lacking a lagoon. However, the archaeology of the latter will also be included in this entry.

Historical Background

Although Micronesian and Polynesian atolls have been the focus of detailed ethnographic research since the first half of the twentieth century, archaeological research lagged behind the work carried out on "high" islands. Initially, archaeological coverage was mainly concerned in documenting surface remains, mostly *marae*, or ritual structures

found in other parts of Polynesia. On atolls, these consist of a rectangular court delimited by low enclosing walls or coral slab alignments, with an elevated altar platform at one end. Shrines of various shapes and sizes incorporating coral and shells (giant clams) are also found on several other atolls. Fish traps built from stacked coral boulders can often be seen on the ocean-side reef flat. Another important feature of the landscape is the presence of extensive pits excavated down to the freshwater lens (Ghyben-Hertzberg lens), occasionally reinforced by coral slabs, to cultivate giant swamp taro (*Cyrtosperma merkusii*).

It was assumed that because of resource limitations, atolls must have been settled after better-endowed volcanic islands had been colonized and human populations pushed the limits of their carrying capacity. In view of atoll geomorphological instability, it was also believed that catastrophic events such as cyclones would have resulted in considerable disturbance of cultural deposits.

It was not until the 1960s, with Janet Davidson's (1971) pioneering excavations on the Polynesian Outlier of Nukuoro in the Eastern Caroline Islands, that the existence of in situ stratigraphy was confirmed. During the following two decades, atoll archaeology progressed, with additional coverage of the Caroline and Marshall Islands in Micronesia, due in large part to the expansion of US federally funded historic preservation programs on islands in free association with the USA. Archaeological discoveries in the Carolines further demonstrated that stratified deposits, albeit disturbed in some cases, could still be identified even on atolls and other island types located in the cyclone belt (Intoh 1981; Leach and Ward 1981). As was the case with most of the archaeology at the time, culture history and questions of origin through the study of artifact types dominated the research agenda.

Key Issues/Current Debates

Recent atoll archaeology has attempted to emulate research carried out on other islands in the Pacific, with attention focusing on the interplay between the environment and humans. Historical ecology (Fitzpatrick and Intoh 2009) has emerged as one of the most useful and comprehensive approaches to understanding how environments (land and seascapes) were affected by climate change/variability, early human settlement, historical interactions, and modern development. Similar to applications in other insular settings, the combination of the natural and social sciences using paleoecology, archaeology, land-use history, and long-term ecological research is potentially informative for examining natural and cultural phenomena behind changes to atoll ecosystems.

Atoll archaeology anchored to an historical ecology approach may lead to a better understanding of the following key issues: (1) the timing of human settlements, (2) paleoclimatology, (3) human impact on resources, and (4) issues of adaptation and sustainability.

Early Human Settlements on Atolls

Islets are geologically young, having developed only in the last millennia (mid-late Holocene). The transition from corals to unconsolidated sediments required for islet buildup varied across time and space, even within the confines of individual atolls, and the emergence of land suitable for permanent human occupation appears to have taken place several centuries later.

In a review of mid-Holocene highstand conditions and their relationship with the timing of human settlement, Dickinson (2003) computed a chronology for the decline of sea levels and the *crossover dates* in different parts of the Pacific island region, finding a close correspondence between the availability of suitable landmass and the first appearance of human activities. The crossover dates specify the inferred time for each island group when declining late-Holocene sea level first carried ambient high tide level below mid-Holocene low tide level. Before the crossover date, relict mid-Holocene paleoreef flats were still overtopped by the sea at high tide. The end of the highstand for Tuvalu, Kiribati, and the Marshall Islands is estimated at 200 B.C., with a crossover date of about A.D. 1100. By contrast, for the Tuamotus in the eastern Pacific, the highstand ends at A.D. 800, with a crossover date of A.D. 1400.

Western Kiribati (Gilbert Islands), together with the Marshall Islands and atolls in the eastern

Carolines, produced radiocarbon dates for human occupation comparable to neighboring "high" islands, between 1,800 and 2,000 years ago, some 500–700 years after the formation of habitable land. Although certainly variable, a time lag is expected for the development of the Ghyben-Hertzberg lens as sea level dropped and conditions changed allowing for sustained land-based livelihoods (Athens 2018).

The Polynesian atolls of Tuvalu, which have received scant archaeological coverage, appeared to have been settled by about A.D. 1000. Farther east, there is evidence for exposed coastal sediments from Kiritimati (Christmas Island), in the Line Islands of Kiribati by about 1000 B.C., prompting some archaeologists to suggest that this large atoll could have been settled during the early Austronesian expansion associated with the Lapita Cultural Complex or later. However, the earliest evidence for human occupation on this and other atolls in the Line and Phoenix Islands only extend back to the twelfth century A.D.

The early dates from eastern Micronesia can be attributed to the greater tidal range in the central Pacific, allowing relict mid-Holocene paleoreef flats to project farther above low tide level, enabling accumulation of unconsolidated sediment to form islets at an earlier stage of sea-level decline. Thus, the absence of intervening stable landforms on the reefs that would later form the atolls of Tokelau and the northern Cook Islands would have effectively isolated the "high" islands of West and East Polynesia, providing a possible explanation for the chronological gap between Lapita settlements in Samoa and the much later dates obtained from East Polynesia and the intervening atolls.

There are controversial dates from Bikini Atoll in the northern Marshalls that may push back settlement to a time coinciding with the Lapita expansion into the southwest Pacific about 3,000 years ago (Streck 1990). Because contamination of carbon samples by modern radioactivity would produce younger rather than older dates, the wood charcoal dates could be derived from old drift logs of long-lived species. Without proper identification, these dates should be considered anomalous. Moreover, this chronology does not match up to the bulk of radiocarbon dates from the Marshalls or elsewhere in Central/Eastern Micronesia (Levin et al. 2019; Poteate et al. 2016; Weisler et al. 2012). Of related interest is evidence for coral island formation on the Jabat, a table reef in the Marshalls, when sea level was rising rather than falling, with supratidal deposits forming as early as 4,500 years ago (Kench et al. 2014). It may that islets on smaller reef platforms predate islet formation on larger atolls, with implications for questions related to the chronology of temporary and permanent human occupation.

Paleoclimatology

There is little direct evidence of the effects of past climates and related changes in vegetation composition or variation in sea level, which may have affected agricultural productivity on atoll societies (Weisler 2001b). Core samples from peat bogs on Teraina in the Line Islands indicated no major vegetation change in the last millennium. Proxy evidence for ENSO variability in the Marshall Islands is attested by tuna remains Lambrides and Weisler 2018).

The abandonment of the Line and Phoenix Islands prior to European contact may relate to increased climatic instability during the mid-second millennium A.D., interrupting long-distance exchanges and leading to declines in land and marine resources, caused by falling sea level (Nunn et al. 2007). Human settlement of these archipelagoes spans the period after A.D. 1000 until A.D. 1600 at a time when people expanded into the marginal East and South Polynesian islands. Long-distance voyaging may have been facilitated by environmental conditions at the time, the Medieval Warm Period, bracketed between A.D. 750 and A.D. 1250 (Nunn 2007:59). However, this scenario has been challenged by climate data from the central Pacific, highlighting the influence of climate variability, at a variety of scales, on Pacific societies and the biota and landscapes with which they interacted.

In eastern Micronesia, initial human settlement about 2,000 years go may be related to heightened ENSO conditions, coinciding with the formation of habitable land on atolls following drawdown of the mid-Holocene highstand.

Human Impact on Resources

An important topic in Pacific Island archaeology is the study of human impact on island ecosystems. Data gathered over several decades of research revealed that indigenous communities significantly altered colonized habitats prior to Western contact. Most of the data are derived from terrestrial ecosystems and include evidence of vegetation burning (charcoal influxes) together with accelerated rates of erosion. Analyses of plant microfossils have also revealed changes in vegetation profiles, although it is not always clear whether these changes can be attributed to human agency, natural causes, or a combination of both. Impacts can also lead to faunal depression, extirpation, and extinction, often occurring in the early periods of human settlement. By contrast, the impact on marine resources is less well documented.

It has been suggested that without significant anthropogenic impact, the islands of Remote Oceania (east of the main Solomon Islands Chain and including all the islands and atolls of Micronesia), would not have been successfully colonized by people lacking a well-established agricultural base. While the importance of food production among early colonizing groups, namely the bearers of the Lapita Cultural Complex still needs to be demonstrated, agriculture expanded later in time. Without a doubt, some of these human-induced impacts had a destructive effect on island biota, but it would be difficult to imagine sustained human livelihoods on atolls in the absence introduced root and tree crops, earning their reputation as "consummate man-made environments" (Kirch 2017:163).

Atoll communities relied heavily on tree crops, such as breadfruit, pandanus, and coconuts, not only to meet their dietary needs but also to supply raw material for a host of products. Perennial arboriculture – agroforestry (the practice of cultivating wild and/or domesticated arboreal species) is a distinguishing characteristic of the earliest agriculture in the Pacific Islands, emerging in the southwest Pacific (Near Oceania) at the end of the Pleistocene, after more than 30,000 years of human settlement. It still constitutes an important component of contemporary atoll landscapes. Several cultivars could be stored, and it may be said that food preservation technology (e.g., to produce fermented breadfruit and dried pandanus paste) reached its zenith on atolls, as people developed ways to process certain foods that could last through periods of scarcity and for use as sea rations.

Agroforestry is a sustainable system of food production by virtue of the relative permanence of land use providing a wide range of subsistence needs, with crops requiring little direct cultivation beyond occasional mulching and replanting. Micronesia's "breadfruit revolution" (Petersen 2006) between 1000 and 1500 A.D. has been explained in terms of the successful hybridization of seeded and seedless varieties originating from opposite directions (western and eastern Micronesia), which enabled population increase and the spread of the Eastern Carolinian matriclan form of social organization, along with political and religious cult practices. Hybrid varieties, which are salt tolerant, provided atoll communities with a major new food source, thus allowing populations to increase.

Another important traditional food, particularly on the wetter atolls, was the giant swamp taro. This member of the aroid (Araceae) family may have preceded human settlement, as indicated by coring records on the "high" island of Pohnpei in Micronesia. Natural dispersal could have occurred by rafting of vegetative parts in clumps of soil protected within roots of drifting uprooted trees. Alternatively, dispersal could have taken place by deposition of fertile seeds from birds' guts.

Pits excavated down to the freshwater lens for the cultivation of giant swamp taro are among the most outstanding anthropogenic features of atoll landscapes. In Kiribati, more than 20 cultivars have been identified, with some varieties grown mainly for prestige and ceremonies. Giant swamp taro cultivation entails a sophisticated system of mulching and fertilization using leaves from a variety of trees. Pits were commonly excavated in the middle of islets where the lens is usually thicker.

Given the dynamic nature of atoll geomorphology, anthropogenic surface remains can easily be obliterated unless located well inland, such as

giant swamp taro pits and associated mounds formed by sediment spoils from excavated pits. Like arboriculture, giant swamp agriculture has a long history on atolls, as illustrated by excavation and dating of ancient surface soils under pit spoil dirt in adjacent mounds (Weisler 1999). One of the first tasks that early settlers were required to perform was to clear vegetation in preparation for giant swamp taro pit digging, because corms (swollen underground plant stems) can take between 9 months to several years to mature. Giant swamp taro tubers have the highest carbohydrate content per unit among the aroids and can tolerate high water levels or even flooding, provided it does not result in an inflow of seawater.

Intensification of food production for giant swamp taro was spatially limited by islet size and thickness of the freshwater lens. As shown by research in the Marshall Islands, continued sea level decline after about 2,000 years ago resulted in land accretion, encouraging people to extend their activity space. Unlike other forms of agricultural intensification such as those practiced on "high" islands, giant swamp taro cultivation did not result in accelerated soil erosion and together with arboriculture constituted a sustainable subsistence practice.

The high ratio of reef to land area, typical of most atolls, provided colonizing groups and their descendants with abundant sources of protein as well as raw material (fish, turtle, and bird bone, coral, beach rock, and shell) for the manufacturing of tools and ornaments. Despite their abundance, marine resources were on occasion subjected to avoidance practices, which would have enabled stocks to recover.

To a large measure, species resilience, together with flexible fishing/shellfish gathering strategies targeting a broad range of taxa, would account for the sustainable use of marine resources (Harris and Weisler 2018; Ono and Addison 2013; Thomas 2014). An exception appears to be the extirpation of the Bullmouth helmet shell (*Cypraecassis rufa*) from Utrōk Atoll in the Marshall Islands (Weisler 2001a), but the overall assessment suggests little change in habitat selection, richness, evenness, or diversity. In addition, the presence or absence of marine species in a particular habitat is partly determined by chaotic and unpredictable recruitment events that shape the structure of reef assemblages over time.

Species resilience is one attribute that may result in sustainability. Nevertheless, even highly resilient organisms can become vulnerable if predation increases because of a growing predator population and/or the introduction of new extractive technologies. The disappearance of large species of giant clams in other insular settings is attributed to their long planktonic stage (allowing for wide dispersal but also resulting in high mortality rates), slow growth, low reproductive success of adults, and sporadic mass mortality in wild populations. It may therefore come as no surprise that some communities resorted to gathering live giant clams from deeper water and transplanting them in "gardens" to locations near the shoreline for later consumption or use as raw material (after removal of the animal), as noted in Kiribati (Gilbert Islands Group – Thomas 2014) and on Takuu Atoll, Papua New Guinea (Moir 1990).

Archaeologists recognize the paucity of data on pre-European contact resource depression, extirpation, and extinction on atolls compared with other island types. In the absence of information on faunal losses in the Line and Phoenix Islands, the demographic histories of these atolls and table reefs cannot be easily explained in terms of anthropogenic change that might have compelled their inhabitants to abandon settlements. In other cases, the timing of species loss remains unclear, for example, the extirpation of rails possibly coinciding with European-introduced invasive mammals.

Adaptation and Sustainability

Research aimed at understanding the relation between the distribution of cultural remains and islet buildup is exemplified by work carried out in the Marshall Islands. Based on an ecological model for atoll settlement and adaptation, the densest (and generally oldest) traces of human occupation are predicted to be on the wider islets, notably in their central portion. This is where the freshwater lens is most developed and thus capable to support agricultural production, especially

giant swamp taro. Moreover, these areas afforded the best protection from salt spray. Other environmental parameters for understanding settlement adaptation include islet location in relation to the prevailing winds, proximity to canoe passes through the reef, and elevation above mean sea level in assessing the risk of damage caused by cyclones and high waves.

However, ecological models of settlement patterns, even for initial settlement, might not adequately explain where people lived in the past. Cultural factors described ethnographically, such as those pertaining to one's status, were shown to determine where high- and low-ranking individual kin groups could establish their residence and organize their activities.

Nevertheless, archaeological data from Ujae and Maloelap in the moderately wet central Marshall Islands show that in the past there was a tendency for settlements to be aggregated into one main village, even on large islets, in association with giant swap taro pits. The habitation area then expanded from the center toward the lagoon, facilitated by land progradation in that direction. Over time, the other islets being smaller were subsequently exploited by people living in the main village for various resources, including birds, turtles, fish, and shellfish, perhaps as a result of a decline in resources near populate areas. It may be that with falling sea level in the mid-second millennium A.D., emerging reef surfaces would have enabled the subsequent development of islets, allowing population dispersal. Later dates for the occupation of smaller islets support this hypothesis (Nunn 2007:145, 147).

Environmental stress, as experienced on many atolls, both in the past and present, can be partly reduced by the use of social capital. Land tenure systems and kinship networks enabled people to maximize choice of residence and group affiliation to access resources. Land tenure systems developed to safeguard terrestrial production among kin groups while also enabling neighboring communities to access resources in times of need. Various cooperative strategies ensured that people could claim rights to resources made possible, for example, by adoption and intermarriage, trade, and sometimes cyclical migrations to alleviate problems of over- and under-population (Alkire 1978). Sustainability could also be achieved by avoidance practices. For example, the concept of *mo* in the Marshall Islands still applies within some inhabited and uninhabited atolls where large bird colonies live and turtle nesting is known. By chiefly decree, northern atolls lacking sufficient rainfall to support permanent human settlement were designated as "game reserves" to be exploited at certain times and in an orderly and ritualized way.

On small islands, including atolls, the need to devise strategies for managing population growth may have arisen quickly, so as not to outstrip resources. Warfare, cannibalism, infanticide, and abortion may have contributed to population regulation, but there were other strategies such as ritual celibacy, prolonged lactation, and adoption. In some instances, under-population may have been a more serious threat to community survival than population pressure. Initially, relatively large families and clans would be necessary to ensure adequate levels of food production. Atoll populations used flexible social processes for the control of fertility and rates of reproduction and actively managed recovery from the demographic challenges of contingency events and ensured their continuity as enduring settlements.

Interisland contacts would confer advantages in the event of demographic instability and shortages of food and raw materials as a result of environmental perturbation, such as that caused by droughts or cyclones. Because of their overall marginality, atolls occupy a prominent position in discussions centered on exchanges with "high" islands. One of the best-documented ethnographic cases of extensive networks was the *sawei*, which hierarchically linked Gagil District on Yap to the atolls of the Western Caroline Islands, a tribute and exchange network spanning more than 1,000 km (Hunter-Anderson and Zan 1996). Although it is unclear when this elaborate network first emerged, archaeologists have found pottery produced on Yap and carried to atolls

some 1,400 years ago. Atolls in the Eastern Caroline Islands, such as Ant near Pohnpei have also yielded basalt artifacts and pottery dating to about 2,000 years ago (Rainbird 2004:163–166). Exotic materials, notably geochemically "fingerprinted" basalt stone adzes have been found in the Tuamotus, Line, and Phoenix Islands, some traced to distant archipelagoes, perhaps via intermediary stops for down-the-line exchanges (Di Piazza and Pearthree 2001; Weisler and Walter 2017).

Atolls were also in contact with each other to form "clusters," as in the Marshall Islands, in light of differences in terrestrial productivity linked to latitudinal variation in rainfall (Alkire 1978). Atolls also differed in size, as well as degree of lagoon closure, shape, and depth, which also affected marine productivity.

Some observers have suggested that people living on atolls were more keenly aware of resource limitations than communities living on lager continental or volcanic islands and thus realized at an early stage the need to conserve resources. In examining the sustainability of natural resource use on atolls, the absence of statistically significant changes in the archaeological record may be indicative of a new number of factors, such as species resilience, diverse extractive strategies, low impact technologies, low human population densities, efficient use of resources (e.g., through an understanding of environmental cues and fluctuations), and the application of intentional and unintentional management practices.

Future Directions

While atoll archaeology in the Pacific has progressed in recent years, there are still a number of questions about cultural development and change, and how these may be linked to various levels of environmental impacts/transformations. As Kirch (1997:18–19) explains in his introduction to a discussion of environmental change and human society in the Pacific Islands, historical ecology aims at understanding "the complex and reciprocal connections linking human populations with the myriad other life forms that share their world." The mutually reinforcing processes of population growth, intensification of production, environmental change, and sociopolitical evolution are relatively well understood on some islands. By contrast, there is little archaeological evidence from atolls that would allow us to draw parallels with some of the "high" islands to further our understanding of the "Big Structures and Large Processes in Oceanic Prehistory" (Kirch 2017:269–287).

That social evolution did take place cannot be doubted, but it appears to be poorly reflected in the archaeological record. Atolls certainly imposed limitations on the range of cultural expressions. Because atolls generally lack monumental architecture indicative of social complexity and their environment severely curtailed further agricultural intensification over time, archaeologists may want to pay more attention to allied disciplines such as historical linguistics and other approaches such as oral traditions to shed light on social transformations that are presumed to have taken place since initial human settlement.

Atolls provide limited potential for intensification of food production using traditional methods. However, studies of atoll agriculture in the Gilbert Islands show that people have over time selected and improved on a variety of tree and root crops, as exemplified by nearly 200 cultivars of pandanus and over 20 varieties of giant swamp taro, differing in quality, taste, and age at maturity. In addition, in the Gilberts, traditional methods of food preservation enabled the accumulation of surplus like on other atolls but were not known to support an elite.

Archaeologists may be able to establish a chronology of giant swamp taro pits, suggesting that expansion of this food production system could be linked to population increase, as argued for the Tuamotus. With a shift in the subsistence economy after Western contact, few giant swamp taro pits were excavated and several were abandoned. Likewise, coral-lined fishponds may indicate intensification of marine food production (Figs. 1, 2, 3, 4, 5, and 6).

Attenbrow, Valerie J.

Peta B. Straiton
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Valerie Jane Attenbrow, also known as Val Attenbrow, is an Australian Archaeologist and Museum Research Scientist at the Australian Museum. Her interests lie predominately in Australian Indigenous Archaeology related to variations in territorial occupation. She graduated in 1976 with an honors degree from the Department of Anthropology at Sydney University. Her Honors thesis examined the Aboriginal occupation of the far south coast of New South Wales, focusing specifically on the subsistence patterns of the Holocene period.

Once graduating, Attenbrow began working as a consultant archaeologist in the Cultural Resources Division of the New South Wales National Parks and Wildlife Service. During this period, and in conjunction with the salvage excavation program for the Mangrove Creek Dam, she began work on the Upper Mangrove Creek catchment area. The results of her excavations provided the necessary momentum for more research and fieldwork in the vicinity, which Attenbrow undertook as part of her Ph.D. at the University of Sydney.

Attenbrow also examined the Aboriginal occupation of Port Jackson and the surrounding Sydney region in 1987–1988 as part of a grant-sponsored project initiated by Hunters Hill Municipal Council. It involved the review of historical documents from the late eighteenth and early nineteenth centuries pertaining to the descriptions of Aboriginal life (albeit not comprehensively) in and around Port Jackson and Botany Bay. Attenbrow began the Port Jackson Project in 1989, which she envisaged would correct the variation present in British records concerning the life and culture of the Aboriginal people in the area. The archaeological evidence she procured through excavations resulted in the development of far more reliable timeframes than the documented evidence, alone, could achieve.

Concurrently, Attenbrow began working for the Australian Museum in its Anthropology Division. Her research since then, which is based at the museum, has seen the completion of several large-scale and successful projects, including the Port Jackson Project and the publication of *Sydney's Aboriginal Past* (Attenbrow 2002). She is now a Principle Research Scientist in the Anthropology Unit, Research Branch of the museum. While at the museum, Attenbrow has continued to analyze excavated assemblages from Upper Mangrove Creek, Port Jackson, and those belonging to other museum collections.

Major Accomplishments

Val Attenbrow's career in archaeology has spanned over three decades and, despite being primarily focused on regional New South Wales, includes other notable contributions to the field of archaeology and a considerable number of published works in the form of books, journal articles, papers, and reviews. In fact, as of early 2011, Attenbrow had a total of 73 published works to her name, both as sole author and coauthor.

Sydney's Aboriginal Past (Attenbrow 2002) is considered to be Attenbrow's magnum opus and represents the culmination of much of her life's

work. The book examines three time periods: pre-colonial (pre-1788), British colonization (at 1788), and early colonial (1788–1820), while the documents she examined in 1987–1988 pertaining to Port Jackson and Botany Bay provide the work's foundation. Within those three time periods, she examines, discusses, and clarifies various issues, including the variation present in British records of Aboriginal life, the array of Aboriginal languages and the barrier this created between the indigenous population and the colonists, and the complex social structures of Aboriginal society. Attenbrow also used her work, in this area, to explore aspects of indigenous life ranging from how food and tools were obtained to the belief systems used in the area and how this affected personal adornment to the use of images and rock art, providing a thorough overview of Aboriginal life in the Port Jackson region.

Some of Attenbrow's other prominent works include *Upper Mangrove Creek catchment* (1988) and *Reduction Continuum and Tool Use* (2005) (coauthored with Peter Hiscock). Her latest publications include a chapter in "Trekking Shore: Changing Coastlines and the Antiquity of Coastal Settlement" entitled *The Role of Marine Resources in the Diet of Pre-Colonial Aboriginal People and Land Use Patters Around Port Jackson, Sydney, New South Wales* (2011). Attenbrow has also been the coeditor of "Australian Archaeology" with Betty Meehan (for volumes 30–35, published from 1989 to 1992) and the editor of "AA Short Reports" (for volumes 42–49, published from 1996 to 1999).

Attenbrow has received a Life Membership Award from the Australian Archaeological Association (AAA) in 2002 and was awarded the Mulvaney Book Award in 2004 by the AAA for her book *Sydney's Aboriginal Past* (2002). Consequently, Attenbrow has not only established herself as an insightful interpreter of Sydney's regional archaeological past but as one who has also contributed substantially to the broader understanding of Australia's Aboriginal past (White 2006).

Aufderheide, Arthur Carl

Dario Piombino-Mascali
Faculty of Medicine, Institute of Biomedical Sciences, Vilnius University, Vilnius, Lithuania
University of Messina, Messina, Italy

Basic Biographical Information

Born in New Ulm, Minnesota, in 1922, Arthur Carl Aufderheide (Fig. 1) studied pre-medicine at Saint Olaf College in Northfield, Minnesota (1940–1942), and medicine at the University of Minnesota, Twin Cities (1943–1946). After

Aufderheide, Arthur Carl, Fig. 1 The late Arthur Aufderheide (1922–2013) during his 2008 field mission in Sicily (image courtesy of the Sicily Mummy Project)

graduating, he took an internship in pathology at the Rochester General Hospital, New York (1946–1947), and subsequently served in the US army, in Germany (Nystrom and Cartmell 2012). During his time in Europe, he participated to a military training program in pathology at the Vienna General Hospital, Austria, followed by a pathology residency at the Minneapolis Veterans Administration Hospital, Minnesota (1949–1952). In 1953, he moved to Duluth, Minnesota, where he became the chief of the Department of Pathology of Saint Mary's Hospital (1955–1974). Additionally, in 1972, he became the head of the Department of Pathology at the newly opened School of Medicine, University of Minnesota-Duluth (Nystrom and Cartmell 2012). Since 1977, he had taught courses in physical anthropology and circumpolar cultures at the Department of Anthropology of the same institution, with the latter reflecting his vivid interest in the Arctic, where he traveled as many as seven times between 1964 and 1980 (Krajick 2005). The new academic position in Duluth required research, but due to the lack of patient care, he decided to concentrate on skeletal biology and paleopathology, focusing on elemental analysis of bone tissue as well as soft tissue abnormalities (Nystrom and Cartmell 2012). In 1982, he traveled to Arica, Chile, in order to attend a short course on paleopathology that was a vital experience for his career. Later, in 1985, he and his wife Mary Lillian Buryk (1923–2017), a registered nurse and musician whom he married in 1946, had their first mummy-hunting trip in South America. There, they obtained soft tissue samples to investigate and analyze, creating a large mummy tissue archive known as the International Mummy Registry, which contained thousands of specimens from several countries around the globe. Between 1987 and 1998, they visited four continents to dissect and sample preserved remains (Nystrom and Cartmell 2012). Since his background lay in medicine, he relied upon autopsy and morphological inspection to identify both pathology and pseudopathology (Nystrom 2015). A decade after his last field mission in Egypt, he journeyed to Sicily, Italy, for an additional mummy expedition sponsored by the National Geographic Society. Shortly afterward, he was awarded an honorary membership by the American Society of Embalmers and the European Academy of Bolzano, Italy, where he and Mary would travel in 2009 for the opening of a mummy exhibition at the South Tyrol Museum of Archaeology. In 2008, he officially retired, becoming an emeritus professor of his university. He died in 2013; he was survived by his wife and three children. In 2017, his mummy dissection kit, which he had left in Sicily some 9 years earlier, was donated to the historical and ethnoanthropological Town Museum of Savoca, where it can be seen on display (Nystrom 2013).

Major Accomplishments

Aufderheide is best known for applying biomedical techniques to spontaneously or

anthropogenically mummified archaeological human remains, demonstrating that invaluable bio-anthropological information can successfully be extracted from such remains (Aufderheide 2003). He also demonstrated that ancient mummies are sources of vital importance to answer specific hypothesis-driven research questions. One major achievement of the scholar was his understanding of the epidemiological pattern of Chagas' disease, a condition determined by the parasite *Trypanosoma cruzi* that affected the populations inhabiting the Pacific coast of Chile and Peru for as much as 9000 years (Nystrom and Cartmell 2012). Specifically, he and his colleagues showed the lack of chronological, demographic, or cultural patterning, suggesting that the disease has maintained a constant prevalence over time. His inspection and study of large numbers of mummified remains also enabled a more complete understanding of mortuary practices, as well as postdepositional changes, and mummification mechanisms, an aspect that he categorized based on his own observations (Aufderheide 2003). In this respect, his 1991 study of the Venzone mummies of northern Italy refuted a long-standing theory, advanced in the nineteenth century, that a fungus was responsible for the mummification process, due to water extraction from the cadavers (Ortner and Aufderheide 1991). His outstanding experience also led to the generation of some of the most comprehensive textbooks on both hard and soft tissue. His *Cambridge Encyclopedia of Human Paleopathology* (Aufderheide and Rodríguez-Martín 1998) was the first reference book where soft tissue abnormalities were described, and popularized the identification of this type of findings among biological anthropologists and bioarchaeologists. This was further expanded in his book on *The Scientific Study of Mummies* (Aufderheide 2003), the most significant reference in the field, which includes a mummy form and a protocol for the quantification of mummy tissue. Later on, in 1998, as a follow-up of his inspection of five Melanesian overmodeled skulls, he developed an interest in this topic, which enabled him to identify a dozen ancient cultures that carried out this unique mortuary ritual aimed at restoring the appearance of the face after death (Aufderheide 2009). He, along with his wife Mary, was instrumental in the establishment of the World Congress of Mummy Studies, the most important venue for scholars involved in the field; the first meeting took place on the island of Tenerife, Spain, in 1992, and the meetings are now (2018) in their tenth iteration, marking the 25th anniversary since its creation. With over 100 academic articles and four books, as well as a vast number of collaborations, he left a clear mark on the history of bioarchaeology and mummy studies. However, it was his great generosity, his willingness to mentor young scholars, and his ability to share his impressive knowledge that continue to live on within the mummy community.

Aurignacian Cultural Unit

Wei Chu and Juergen Richter
Institute of Prehistoric Archeology, University of Cologne, Cologne, Germany

Introduction

The Aurignacian is an early Upper Paleolithic cultural unit from the middle of the Last Glacial Period (c. 43–35 thousand years before present; ka B.P.) originally identified in southwest France. It is currently known to be largely distributed from the Lower Don Valley in Eastern Europe to southern Great Britain and the Ebro River Valley in Spain. There are other sites with later ages (34–26 ka B.P.) and those found farther afield, but their chronology, attribution, and stratigraphic integrity are often unclear (Fig. 1). The bearers of the Aurignacian cultural unit are thought to have primarily inhabited glacial steppic landscapes and archeological assemblages are frequently associated with butchered horse, reindeer, and mammoth remains.

The Aurignacian marks the onset of the Upper Paleolithic and is connected to some of the earliest regional blade (lithic blanks that are at least twice as long as they are wide with parallel longitudinal edges and at least one ridge on the dorsal face) and bladelet (small blades >10 mm in width) technology and is generally accepted as a proxy for the first expansion of modern humans into western Eurasia (Bar-Yosef and Zilhão 2006). The Aurignacian is also known for its bone industry, decorative personal ornaments, and abstract/figurative artforms. It is thought to succeed the Middle Paleolithic Mousterian and transitional cultural units (e.g., Châtelperronian, Szeletian, Lincombian, Jerzmanovician) and precede the Gravettian cultural unit.

Definition

Archeological assemblages are conventionally assigned to the Aurignacian cultural unit by the presence of certain stone and bone tools (Fig. 2). However, assemblages have also been ascribed to it by analyzing the operational sequences (*chaîne opératoires*) of assemblages to reconstruct the chronological ordering of the different steps in reduction strategies. Aurignacian stone technology is characterized by the use of flakes and blades as blanks for "formal tools." Whereas blades were the exclusive blank production method during the later stages of the Upper Paleolithic (*serial* production), Aurignacian lithic production relied on an *assortment* of different blank and blade forms that it shares with the preceding Middle Paleolithic Mousterian or Micoquian (*Keilmessergruppen;* Richter 1997: 253).

Formal tools used as decisive criteria to identifying the Aurignacian are:

- Carinated scrapers – bladelet cores mostly effectuated on thick flakes that may have also been used as tools.
- Bladelets laterally blunted with alternate, inverse, or direct retouch (Dufour bladelets, Font-Yves/Krems points) produced from prismatic/pyramidal cores or carinated scrapers.
- Bone, antler, and ivory tools in the forms of split-based, massive-based, simple-based, lozangic and double bevel-ended (biconical) points with rhombic outlines.

Additional criteria include:

- Thick elongated blades with steep, sometimes scaliform edge retouch (*Aurignacian retouch*).

Aurignacian Cultural Unit, Fig. 1 Map of reported sites attributed to the Aurignacian in Europe with 80 m coastline outlined in light blue. (After Schmidt and Zimmermann 2019; data available at https://doi.org/10.5880/SFB806.42)

On some of these blades, Aurignacian retouch is found along the midsections of both lateral edges to produce "waisted" or "strangled" forms.

- Burins – flakes with a narrow, sharp edge at the tip produced by striking a small flake obliquely from the edge of the burin flake. Characteristic Aurignacian burin forms are the busked (*busqué*) and Vachon type burins made from blades or thick flakes.
- Endscrapers – flakes or blades modified at their distal end by removing parallel scars to shape a convex edge. Specific Aurignacian endscraper subtypes include atypical carinated, thick nose-ended, shouldered (or flat nose-ended), nucleiform, and rabots.
- Personal ornaments in the form of pierced tooth, shell, bone, and stone beads. Characteristic Aurignacian forms are varied and demonstrate distinct spatiotemporal varieties (e.g., basket-shaped) and production methods.
- Abstract and figurative mobiliary and parietal artforms representing human and animal forms and bone flutes pointing to an early musical tradition.

Historical Background

The Aurignacian cultural unit was named after the Aurignac rock shelter (Haute-Garrone, France) discovered in 1852 and later studied by É. Lartet. At the turn of the twentieth century, the Aurignacian was formally described by H. Breuil and E. Cartailhac who defined three successive phases: the Ancient, Middle, and Upper Aurignacian covering the first half of the Upper Paleolithic typological succession.

In the 1930s, following excavations at the site of La Ferrassie (Dordogne, France), D. Peyrony redefined the Aurignacian to apply (Karavanić 2000; Patou-Mathis et al. 2016) solely to Breuil and Cartailhac's Middle Aurignacian phase ascribing the Ancient Aurignacian to the Lower Perigordian (today known as the Châtelperronian) and the Upper Aurignacian to the Upper

Aurignacian Cultural Unit, Fig. 2 Index fossils of the Aurignacian: (1) carinated scraper: (2) carinated nosed scraper; (3) nosed scraper; (4) Aurignacian blade; (5) strangulated blade; (6) Dufour bladelets (a-Dufour subtype; b-Roc de Combe subtype); (7) Fonte-Yves bladelet; (8) spit-based point; (9) Busqué burin; (10) Vachons burin; (11) flattened lozangic point; (12) oval-sectioned lozangic point; (13) biconical point. 1–7, 9–11, 13 after Davies 2001 and 12 after Albrecht et al. (1972) Taf. 2

Perigordian (today known as the Gravettian). Peyrony maintained the contemporaneity of the Perigordian and Aurignacian Upper Paleolithic cultures in southwest France and subdivided the main divisions of his scheme based upon the French sites of La Ferrassie and Laugerie-Haute (Dordogne): the Lower Perigordian containing two phases (I–II), the Aurignacian having five (I–V), and the Upper Perigordian covering three (IV–VI). It was later argued that many of

Peyrony's assemblages were stratigraphically mixed and that the retouched bladelets found within the Perigordian II assemblages were more akin to Aurignacian assemblages. Based on its inferior stratigraphic position at sites in southwest France, the Perigordian II was therefore assumed to precede the earliest Aurignacian phase (Aurignacian I) and was renamed the Aurignacian 0. These assemblages frequently contained fewer and less elaborate types and absolute numbers of bone and stone tools than the Aurignacian I suggesting a development of the Aurignacian over time. Later, based on his excavations at Abri Mochi in Liguria (Italy), G. Laplace argued for two diachronic phases: the Protoaurignacian and archaic Aurignacian that roughly correspond with the Aurignacian 0 and I scheme (Laplace 1966).

It is worth noting that this historical background provided summarizes the evolution of the French school given the importance of the initial discovery of the eponymous assemblage in France and the large number of sites and breadth of research. Nevertheless, Aurignacian research elsewhere in Europe has a long history that did not always develop in parallel and thus may reflect different past trajectories.

Key Issues/Current Debates

Variants of the Aurignacian Across Time and Space

Today, the Aurignacian is separated into many variants that are thought to be temporally or spatially meaningful. The first is the **Protoaurignacian** (i.e., Proto-aurignacian, Fumanian) characterized by the production of large (c. 30–45 mm), straight bladelets (subtype *Dufour*) from prismatic and pyramidal cores seen by some as the oldest phase of the Aurignacian.

In southwest France, northern Italy, and Spain, when found together, the Protoaurignacian is always superimposed by the **Classic (Early) Aurignacian** where bladelets are generally produced from carinated cores. This production method resulted in smaller bladelets (c. 15–20 mm) with characteristic "twisted" profiles that were often retouched into Dufour bladelets (subtype *Roc du Combe*). However further east, where the Protoaurignacian is less known, Classic Aurignacian assemblages often directly follow the Middle Paleolithic and so-called transitional industries and are associated with radiocarbon dates as old as the first occurrence of the Protoaurignacian in the Mediterranean thus making it difficult to simply consider the two assemblages as successive stages of the same cultural unit (Banks et al. 2013; and comments).

It is also thought by some that the Classic Aurignacian later grew into the **Late (Evolved) Aurignacian** that is defined as having a larger, more varied tool kit including (backed) microblades. However, such assemblages often share many cultural traits associated with the Gravettian, possibly relating to mechanical admixture, or suggesting that they represent a distinct cultural phenomenon.

A further cultural unit, the **Olschevian** was originally defined as a similar, yet discrete cultural unit based on osseous tools with less significant stone tools. In recent years, the Olschevian has been largely subsumed under the Aurignacian nomenclature and is now seen as a regional expression of specialized hunting sites of an Eastern Alpine subgroup (e.g., Olseva, Mokriška caves) of the Aurignacian cultural unit.

The **Levantine Aurignacian** is another classification for mostly younger lithic assemblages found along the coastal Levant in Israel, Lebanon, and possibly Turkey and Syria (e.g., Yabroud, Umm El Tlell, Ksar-Akil, Kebara, Üçağızli). Still, the Levantine Aurignacian is technologically and geographically poorly understood and its relationship to other Upper Paleolithic cultural unit including the European Aurignacian is still unknown (Williams 2006). It shares only some of the hallmarks of the Aurignacian, with a spatial gap of over 1000 km and radiometric dates significantly younger than the European Aurignacian (the "Levantine Aurignacian" seems to start around 38–34 ka B.P. – the time when its European counterpart terminated). The more the Levantine Aurignacian is technologically and geographically better understood, the more

questionable its relationship to the European Aurignacian has become (Williams 2006).

For completeness, we must mention a number of terms that are currently out of favor yet are still present in the preexisting literature. The first of which is the **Pre-Aurignacian,** a term that was originally defined as a Middle Paleolithic blade industry understood as a harbinger of the Aurignacian by A. Rust when he excavated Yabroud rock shelter (Rust 1950). This term is now seen as synonymous with the Amudian cultural unit that is more than 200 ka B.P. and may relate to the earlier Hummalian cultural units.

Other terms are the **Epi-Aurignacian/Aurignacian V** that comprise assemblages with Aurignacian-like carinated elements. These few sites, ranging from Portugal to Eastern Europe, were originally thought to have been part of a final stage of the Aurignacian cultural unit (c. 25 ka B.P.) following a curious temporal hiatus. Today, these units are seen as an independent cultural unit associated with the poorly understood transition from the terminal Gravettian to proto-Solutrean cultural units (Verpoorte et al 2019).

Who Made the Aurignacian?

The predominant theory is that the Aurignacian is the first cultural unit manufactured exclusively by modern humans in western Eurasia because of the similar chronology of the archeological assemblages and modern human fossils (Churchill and Smith 2000; Hoffecker 2009). Still, there are few well-excavated sites containing associated Aurignacian artifacts and hominin remains. Early fossils accompanying Protoaurignacian assemblages are reported in western Eurasia at Le Piage (France), Riparo Bombrini (Italy) and Fumane (Italy), and Isturitz (France), though the attributions of the lithics to the Protoaurignacian, the fossils to modern humans or the association between the two might remain debatable in some cases.

Similarly, modern human remains in subsequent Classic Aurignacian/Aurignacian-like contexts are also rare but those found at Kostenki (Russia), Bacho Kiro (Bulgaria), Deravá Skala (Slovakia), La Ferrassie, Fontéchevade, La Quina Aval, Brassempouy (France), and Fossellone (Italy) suggest stronger evidences.

After 35 ka B.P., more complete modern human specimens from sites in France, Germany, Czechia, Hungary, and Romania are better known. Of particular interest is the site of Mladeč (Czechia) where dates (c. 35.5 ka B.P.) from unambiguous modern human samples are associated with Aurignacian artifacts. At Muierii, Cioclovina (Romania), Istállós-kő and Görömböly-Tapolca (Hungary), modern human fossils are well known and well dated though their provenance and association with the small Aurignacian assemblages is equivocal. In Western Europe, cranial fragments and teeth coming from Aurignacian-bearing layers have been found in France (La Crouzade, Les Rois, and La Combe) and Germany (Hohlenstein-Stadel, Sirgenstein, Kleine Ofnet, Schafstall, and Geißenklösterle; Hublin 2015).

When Did the Aurignacian Start and How Did It Spread?

If the Aurignacian cultural unit is associated with modern humans, then the origin of the Aurignacian through space and time is a key issue to understanding modern human dispersals into and across Eurasia. Many authors would suggest that the Protoaurignacian originated around 43 ka B.P. and was replaced by the Classic Aurignacian at around 38 ka B.P.

There is also debate concerning the age of the Protoaurignacian as possibly contemporaneous with the beginning of the Classic Aurignacian (Nigst et al. 2014), thus assigning regional roles to both phenomena. The dating of major Classic Aurignacian sites is often still disputed, but many authors would agree that the Aurignacian cultural unit was firmly established across western Eurasia by around 38 ka B.P.

Some authors have classified all Aurignacian assemblages earlier than c. 41.5 ka B.P. as Upper Paleolithic cultural units preceding the Aurignacian, postulating that they may even have been made by Neandertals rather than modern humans (Zilhão and d'Errico 1999). This would favor a dispersal/replacement model though there is little indication of technological and typological

continuity with the local European Mousterian cultural unit. The Classic Aurignacian is also remarkably consistent across Europe and we have no concrete evidence of the polycentric development of various diagnostic Aurignacian attributes (Davies 2001).

Where Does the Aurignacian Originate From?

A prevalent model suggests that the Protoaurignacian originated from the Early Ahmarian Upper Paleolithic cultural unit in the Levant some 43 ka B.P. based on the production of similar fine blades and bladelets. However, the Early Ahmarian Cultural Unit is rather heterogeneous and a paucity of robust chronology allows for multiple interpretations as to the whether the Early Ahmarian was indeed a progenitor to the Protoaurignacian. A contrasting view is that the Aurignacian arose within Central and Western Europe, developing out of local preceding transitional industries (e.g., Châtelperronian) and/or Initial Upper Paleolithic (e.g., Bohunician, Streletskayan, Kozarnikian/Bachokirian) cultural units that were manufactured by modern humans possibly mirroring an in situ biological evolution from Neandertals to modern humans (Bar-Yosef 2006) or a vice versa acculturation process.

Others have suggested that the Aurignacian originated on the Central Asian Plateau from the Zagros Aurignacian/Baradostian/Rostamian cultural units (e.g., Shanidar, Yafteh, and Warwasi) that in turn evolved from the preceding local Mousterian traditions, though it is not entirely clear if this observation is a result of stratigraphic mixing or the result of distinct, yet contemporaneous hominin groups (Otte 2014). A single modern human tooth was identified in association with a Baradostian assemblage at Eshkaft-e Gavi, though there are no reliable associated age estimates. Small assemblages from Iran, Iraq, and Afghanistan demonstrate similar flake, blade, and bladelet reduction strategies that produced retouched bladelet forms described as Arjeneh points (similar to the El Wad points of the Levantine Aurignacian) and Dufour bladelets, accompanied by carinated endscrapers and burins that may have technological links to the Levantine and European Aurignacian (Olszewski and Dibble 1994).

Other evidence from the Altai Mountains also suggest that the local Middle Palaeolithic gradually evolved into the Initial Upper Palaeolithic (Kara-Bom variant; c. 42 ka) and the Early Upper Palaeolithic (Ust-Karakol variant), the latter of which contains many Aurignacian-like forms (e.g., carinated scrapers, bone tools, and personal ornaments) implying a convergent emergence of modern human anatomical and behavioral features (Derevianko and Shunkov 2009). Still, stratigraphic mixing has questioned the validity of this in situ transition and the dating and attribution to specific hominins remains an open question. One possibility is that the Upper Palaeolithic developments in the Altai were made by modern human hybridization given the abundant evidence for species interbreeding. At a minimum, such research highlights the vast amount of archaeological research that still needs to be done further east.

If Aurignacian origins indeed lie in the Levant or further east, then the mechanisms underlying how it spread westward to Europe has been a central question in recent years with no clear consensus of if migration occurred as a wave, as an axial route and if modern humans moved along the European interior via the Russian Plain, followed major waterways such as the Danube catchment, or along the southern Mediterranean coastal edge. One theory proposes the various Aurignacian subdivisions may have developed in different geographical domains and that the Danube represented a preferential corridor for the diffusion of Classic Aurignacian cultural unit (Conard and Bolus 2008), while the Mediterranean coastline was followed by makers of Protoaurignacian cultural unit (Mellars 2006). However, the inability to prove any supraregional internal chronology of the Aurignacian poses a major obstacle in tracing its place of origin.

Why and How Did the Aurignacian Develop?

Generally, in Western Europe (from the Upper Danube to the Ebro), the Aurignacian is seen as

an intrusive entity linked to a population change from the last Neanderthals (the bearers of the preceding Châtelperronian) and early modern humans as bearers of the Aurignacian. By contrast, archeologists working in Central and Eastern Europe underline the role of "transitional industries" in triggering the emergence of the Early Upper Paleolithic with possible shared zones of contact between Neanderthals and modern humans. Moreover, across Europe, evidence is growing for the intensification processes already visible during the late Middle Paleolithic, such as bladelet production, tool curation, bone tool use, prey diversification, regional traditions, and population growth.

A decade ago, some scholars objected to the perception that modern humans might have acculturated native Neandertal populations with Upper Paleolithic innovations such as symbolism and suggest that Neandertals could have inculcated incoming modern human populations with Upper Paleolithic behaviors. Such a reinterpretation depends upon reassessing the available evidence, especially that from the earliest phases of the Aurignacian in Europe, and particularly in Central and Eastern Europe. Protoaurignacian assemblages are especially vulnerable to such reinterpretations because of their small sizes and low typological diversity.

It has long been suggested that Neandertals were influenced by the incoming modern human Aurignacian groups. Since the discovery of the St. Césaire fossils in 1979, the Châtelperronian has been associated with that Neandertals, while the skeletal remains we have for the Aurignacian suggest a comparatively robust connection between the Aurignacian and modern humans. The Croatian site of Vindija, containing an apparent connection between Neandertal remains and Aurignacian osseous points, has been used by some researchers to question the validity of this consensus and the typological and technological discreteness of the Aurignacian. However, the atypical composition of the Aurignacian assemblages at this site has led researchers to question the nature of the association.

International Perspectives

The study of the Aurignacian and by association, the first modern human peopling of Europe is important to understanding the processes of colonization and sustained occupation of the edges of the Eurasian continent through a diverse geological region with different biomes during a period of dramatic climatic changes where a well-understood preexisting hominin population was already present. In some regions, such as southwest France, Moravia, and southern Russia, the number and size of archeological sites constitute a large enough sample to draw meaningful conclusions about the nature of the Aurignacian. In others, for example, parts of Eastern Europe, Western and Central Asia, Russia and coastal Europe, the few-known instances do not easily render themselves for behavioral or chronological interpretations. Additionally, many of the famous Aurignacian sites were excavated in the past when methods and techniques were disparate, making it difficult to extrapolate data and compare assemblages. Thus, a main goal of the future research is to understand the compositional integrity and standardization of the Aurignacian systematics from Western Europe. Surprisingly, the current Aurignacian debate still focuses mostly on typochronology and punctual scientific results (radiometric dating, DNA-analysis, isotope studies, etc.), neglecting ample available information on intra-site variability, human mobility, and annual cycles of seasonally induced behavioral patterns.

Future Directions

The main goal of Aurignacian studies is to ascertain its deeper meaning for modern human prehistoric life. Two lines of evidence that are crucial to this understanding are found in better chronological and spatial control that require continued focus on site and assemblage integrity alongside in-depth analyses of recently excavated assemblages and existing collections.

A matter that still needs clarification is identifying the stimuli that elicited the Aurignacian and determining what allowed it to spread so rapidly.

Key to this is establishing the reasons for the different data between various Aurignacian assemblages through time by investigating the development of these cultural units from regional perspectives. It is still unclear whether all the cultural unit described as Aurignacian are the same or if earlier assemblages (e.g., Early Ahmarian) are comparable to the later ones. The range of technologies at the beginning of the Upper Paleolithic could be explained in several ways. Among them, the rapid adaptation of the bladelet concept and the introduction of new bone tools may have played major roles. High levels of modern human mobility may have also permitted cultural interactions between different regional groups with exchanges of technological knowledge over large territories. In this regard, the association of the Aurignacian cultural unit with the spread of modern humans requires the design of a large-scale study that compares Eurasian early and initial Upper Paleolithic cultural units, such as the Baradostian, Rostamian, Early Ahmarian, and Emiran.

Part of understanding the development of the Aurignacian through time also involves discerning what early steps were necessary for its phylogenetic change. This includes identifying environmental/cognitive changes and the modes of cultural transmission that allowed it to develop and pinpointing when and where these steps took place. Answering such questions are found in a wide range of ongoing palaeoenvironmental, cognitive, and experimental research.

A further line of investigation necessitates identifying the specific functions of Aurignacian assemblages and how they impacted hominin survival and reproduction. For example, it has been long suggested that osseous points and bladelets were used as armatures for composite weaponry. However, it is still unclear if this was the case and/or how they may have been used. Such answers lie within the growing body of functional analyses of newly excavated assemblages that employ the advancing techniques in micro-wear, residue, and technological analysis.

Another important part of understanding the Aurignacian or the Upper Paleolithic more broadly rests on deciphering the evolutionary history of the cultural unit. This includes determining how it compares to the other toolkits and subsistence strategies employed by contemporary related species that may help to understand the mechanisms that allowed it to rise. Part of this involves decoding why the Aurignacian and laminar technology in a broad sense evolved in the way it did and not in another.

The lithic and osseous assemblages provide only a small window into early Upper Palaeolithic technological solutions and therefore struggle to reveal other aspects of the human past. If the Aurignacian Cultural Unit indeed represents a distinct ethno(linguistic) group, then there are a number of associated findings that can contribute to our understanding of Aurignacian behavior. The growing corpus of Aurignacian-associated parietal and mobiliary art appears to contain broad stylistic (e.g., pointillistic, dotted or dashed lines) and thematic (figurative, large animals; vulvae) threads (though with notable differences, e.g., between the Swabian Jura and southern France) linking artworks across Europe. These raise questions of rituals, religion, social connections and may provide insight into the way early humans perceived the natural environment. The associated human burial at Kostenki, (and to a lesser extent Mladeč) may likewise reflect possible changes in mortuary behavior. However, given the dearth of archaeological evidences, robust answers to these issues lie in increased transdisciplinary approaches.

Finally, the locations and configurations of Aurignacian sites, sometimes with features suggestive of dwelling structures invite discussions concerning settlement patterns, demography, and ecology. Such approaches are still challenging due to our current understanding of chronology and site preservation, but advances in geomorphology, experimental archaeology, and site formation processes on both local and regional scales may ultimately help to resolve some of these issues.

While the current coarse-grained record still permits several scenarios for how the Aurignacian formed and spread, the current data still points to

an origin rooted in the Levantine or Western Asian Initial Upper Paleolithic. The development to the Aurignacian seems to have been triggered by early arrivals of modern humans either indirectly or directly after ca. 43 ka in Europe. Still, while it may be tempting to attribute Aurignacian cultural unit subdivisions to different populations, genetic admixture is proving increasingly multifaceted and relating assemblages to specific hominin groups is becoming increasingly problematic and complicated.

Australasian Historical Archaeology

Alan Hay
Austral Tasmania Pty Ltd, Hobart, TAS, Australia

Introduction

Australasian historical archaeology is a diverse field of archaeological techniques and knowledge focused around the settler societies of Australia and New Zealand. This appellation not only echoes a shared colonial past between the two countries but also demarcates a common disciplinary milieu, a milieu which has seen increased collaboration in recent decades. In the practice of Australasian archaeology, the subfield of historical archaeology commonly relates to the study of a period beginning with the arrival of the first Europeans who came with the intent of colonizing Australasia. However, the boundaries of the subfield are not always clear or uncontested and are subject to redefinition as new techniques are adopted and new understandings deployed. Maritime history constitutes an important part of the colonial story in Australasia, and maritime archaeology overlaps with historical archaeology owing to shared research methods and a similar time frame (Burke and Smith 2007: 215). Therefore, any general consideration of Australasian historical archaeology must be undertaken alongside a consideration of Australasian maritime archaeology (Lawrence and Davies 2009: 629).

The colonial pasts of New Zealand and Australia stem from similar origins within the British diaspora, and these pasts are considerably intermingled, although the initial colonies can be readily understood to have differing populations, since Australia was a penal colony and New Zealand began as a settlement with free settlers. The first flow of population to the east coast of Australia in 1788 over 40 years before New Zealand was vigorously colonized and also means a difference in the length of colonial development. Furthermore, each society and region in Australasia were radically altered by the response of Indigenous peoples to colonization. The range of Indigenous responses has resulted in widespread variation, not only between the two countries but also within them. It should also be understood that strong ties still exist between the history and current societies of the two countries. Most of New Zealand was part of the colony of New South Wales until 1825, and the flow of free settlers increased in Australia at around the same time that substantial levels of immigration began in New Zealand. Each country also pursued similar strategies of domination in an attempt to control and subjugate the Indigenous inhabitants of Australasia. The countries were drawn together more tightly through the nineteenth and twentieth centuries and their shared heritage, and geographical proximity has led to strong cultural similarities. Importantly, the diverse background of immigrants to Australasia from all over the world means that it has a broad multicultural composition.

Although there are a number of succinct and instructive descriptions of Australasian historical archaeology as a discrete entity (e.g., Lawrence and Karskens 2003; Lawrence and Davies 2009; Paterson and Heath 2009), the historical archaeology of Australia and New Zealand has not been subjected to an exhaustive, unified analysis. This is as much a result of the distinctive development

of the discipline within each country as it is of different frames of reference currently at work. A noticeable lack of a shared comprehensive self-reflection underscores a current effort within Australasian historical archaeology to implement studies of a broader geographical scope as a starting point for wider discussions. This effort is a sign of a growing regional "Australasian" consciousness within the subfield, fostered in part by the Australasian Society for Historical Archaeology (ASHA) and the Australasian Institute for Maritime Archaeology (AIMA).

Despite a group of studies undertaken in the early twentieth century in New Zealand by the anthropologist Elsdon Best, the discipline principally flourished throughout Australasia from the start of the 1960s. This began with an awakened understanding on behalf of scholars that the material culture of the historical period was useful in answering research questions, even if these questions were only a subordinate interest to their concerns about the ancient past. This academic awakening was soon spurred on by changes occurring within wider society. In both countries, the burgeoning public interest in national history led to historical heritage receiving legislative protection from national and regional governments. This legislation encouraged the growth of professional historical archaeologists who were capable of meeting the new legal requirements for both government and private organizations. The growth of archaeological consultants within historical archaeology, and consequently the increase of reports intended for private consumption rather than publication, has led to the expansion of a considerable body of gray literature. Although there are some studies that have moved to change this, such as the work of the Archaeology of Sydney Research Group that promotes research and publications from consultant archaeologists as well as academics.

Statutory bodies in both Australia and New Zealand are responsible for the protection of historical archaeological heritage and of ensuring adequate standards in historical archaeological practice. This position is chiefly occupied in New Zealand by the New Zealand Historic Places Trust and in Australia by the Australian Heritage Council and smaller state bodies. Legislations such as the *Resource Management Act 1991* and the *Historic Places Amendment Act 1975* in New Zealand and the *Environment Protection and Biodiversity Conservation Act 1999* and a variety of state acts in Australia provide statutory frameworks for the protection of historical heritage. There are also a number of non-statutory bodies like the National Trust, Australasian Society for Historical Archaeology (ASHA), Australasian Institute for Maritime Archaeology (AIMA), Australian Archaeological Association, and New Zealand Archaeological Association that promote the protection of historical archaeological heritage. Various local and community groups throughout Australasia also take an interest in protecting the historical archaeological heritage that they are most connected with.

Definition

Australasian historical archaeology is the study of the colonial past of Australia and New Zealand through the investigation of material culture. The time frame that is studied commonly extends from 1788 to the present day, and it can be seen that historical archaeology in Australasia is largely based on an event, the annexing of land by European colonists, rather than criteria concerned with an arbitrary "documentary" threshold of historicity in society. The legislative and practical framework constructed around Australian and New Zealand territory means that the vast majority of Australasian historical archaeology is physically placed in Australasia.

The temporal focus of historical archaeology in Australasia is primarily from the beginning of serious colonization onward, although periods of exploration of the region by Europeans and interactions between Indigenous Australians and Indonesian peoples occurring as far back as the beginning of the seventeenth century are often included. The Makassar seasonally visited the north coast of Australia in search of the *trepang* (sea cucumber) since at least the eighteenth century and the Dutch explorers left their material culture, often in the form of shipwrecks, along the west and north coasts of Australia since the seventeenth century. The sometimes implicit

emphasis on the arrival of the colonizers often means that in practice, there is a sharp distinction drawn between Australasian historical and Indigenous archaeology, a distinction reinforced by legislation and cultural heritage management frameworks. This division is particularly the case in Australia but less so in New Zealand where historical period Māori sites were first investigated in order to better understand the precolonial past (Smith 1991: 8). This interest in Indigenous cultural continuity across the barrier of European colonization has been sustained throughout the history of New Zealand historical archaeology. Contrarily, only recently has there been an attempt to return an understanding of Indigenous Australian people to the historical landscape in Australia. This attempt has arisen largely from assertions by Indigenous Australians that their histories did not cease with the arrival of the colonists. This means that the temporal boundary between "prehistoric" and historical Australasia is far from fixed, even less so than the temporal boundary between precolonial and colonial Australasia, despite what has often been believed.

The spatial scope of Australasian historical archaeology is directed primarily to the mainland of Australia, Tasmania, the North and South Island of New Zealand, and a number of other islands scattered throughout the Pacific. Australia and New Zealand also lay claim to portions of the Antarctic, and the material remnants of scientific exploration receive archaeological attention from both countries. The Australasian geopolitical area is critical to the practice of historical archaeology, and much research relies on government funding or government-backed regulators. Important archaeological sites spread throughout the world are associated with the history of the ANZACs, Australian and New Zealand soldiers who fought alongside one another in the First World War. The story of the ANZACs constitutes a history that is critical to centralizing and unifying national identities in both countries, although many archaeological sites are located outside of Australasia. While the geopolitical boundaries of the Australasian region are important in maintaining and fostering the subfield, the global dispersal of Australasian historical archaeological sites means that the scope of Australasian historical archaeology is global.

Broad concepts like capitalism and immigration provide the bedrock of analysis in Australasian historical archaeology, yet it also makes use of a wide variety of more specific themes and categories to control and understand its data. These are somewhat arbitrary, and entirely open to question, these concepts help structure the investigation and provide a measure of comparison that is becoming more and more critical to the subfield. There are as many different categories of site "as there are different types of human behavior in the past" (Burke and Smith 2007: 196), yet a broad enumeration will give an idea of what comprises the regular subject of historical archaeological discourse in Australasia.

An important first step in the use of categories in Australasia is usually the sketching of cultural boundaries interior to Australasian society. This is largely to do with the broader area of knowledge that the site can then be placed in and the resultant ease of comparison that the framework of knowledge then provides (Smith 2004: 260). The rich multicultural background of Australasia means that the cultural groupings are many and varied, with some examples of cultural groupings often deployed being Indigenous Australian, British, Chinese, Irish, Dutch, German, and Māori. An example of the multiplicity that is encountered once the above broad categories are investigated more closely is seen through the use of the concept of Indigenous Australian cultural identity in the analysis of the historical period. With hundreds of Aboriginal nations, each cultural group is distinct and possesses its own language or dialect and its own worldview. Further evidence of the mutability of these categories can be seen in work relating to Chinese immigrants in the Australasian goldfields in the nineteenth century. These immigrants tended to come from southern China's Guangdong province, and their language was Cantonese rather than Mandarin. Selecting the right cultural framework with which to interpret results is often a matter of accurate historical research and the correct scale of analysis. Cultural categories such as these are often employed simultaneously across a variety of site types.

Australasian Historical Archaeology, Table 1 A selection of subjects, themes, topics, and site types in Australasian historical archaeology. (Slightly modified and heavily abbreviated from Schacht 2010)

Examples of subjects	Examples of themes	Examples of sites
Settlement	Cross-cultural encounters	Trading station, mission station, rock-shelter, campsite, and rural estate
	Convicts and incarceration	Convict households, squatters' estates, prisons, female convict factories, and convict ships
Development	Defense	Battlefields, hangars, airfield bomb shelters, Pa, and searchlight bunkers
	Infrastructure and transport	Wreck site, shipyard, dry dock, road verge, tramway, and rail bridge
People and society	Status and class	Schools, churches, urban houses company offices, and cemeteries
	Ideology, cult, and religion	Churches, mosques, temples, Bora rings, cricket pitch, shrine, and town halls
Economy	Primary industries	Quarry, mine, farm, sealers camp, logging camp, and tryworks
	Consumption	Corner shop, urban house site, warehouse, wreck site, quay, and farmhouse

These site types cut across the broader category and tend to reflect the masculine occupations of the past to the exclusion of historical actors who were not adult males (Burke and Smith 2007: 208). Although this is true, when this typing is considered in the broadest possible fashion, a consideration of these types helps to flesh out any definition of Australasian historical archaeology, even if only to characterize the content of how the past is constructed by historical archaeologists in Australasia. A framework produced by Ilka Schacht (2010) for a thematic research framework in Australian archaeology provides a good starting place for this understanding, and Table 1 is a small selection of subjects and themes drawn from this work with the addition of some New Zealand examples.

Historical Background

An incipient investigation of historical sites was evident in Australasia as early as 1921, yet it was only in the 1960s that systematic historical archaeological work began to be undertaken by academic and museological institutions. The first studies contained significant elements of post-contact, industrial, military, and, in Australia, maritime archaeology. Owing to a growing historical consciousness in Australasia, there was a broad enactment of legislation protecting historical heritage from the 1970s. This legislation spurred an increase in archaeological activity in Australia and New Zealand through the 1970s and 1980s, with the former country emphasizing the role of private consultants and the latter that of government-employed archaeologists (Smith 1991: 8; Lawrence and Davies 2011: 12). From the early 1990s, formal steps were taken to solidify the links between Australia and New Zealand, and studies with a wider regional focus were completed. The varied development of historical archaeology in Australasia has shaped the current debates and areas of concern within the discipline today.

The earliest form of historical archaeological thinking in Australasia was the investigation of colonial era Māori *Pa* and British military fortifications by the anthropologist Elsdon Best in New Zealand in the 1920s (Smith 1991: 6). Although relying heavily on historical sources and producing work of a primarily descriptive nature, Best dealt with sites from the colonial period and explained structural changes in Māori military fortifications (Smith 1991: 6).

In 1959, archaeologists in New Zealand excavated a series of deposits dating from the nineteenth century Māori site at Orongo Bay, Gisborne, deposits that were superposed over earlier prehistoric deposits (Smith 1991: 7). Later in 1959 and 1960, excavations were undertaken at the site of the British military's Paremata Barracks

near Wellington (Smith 1991: 7). In New Zealand in the 1960s, investigation was focused mainly on post-contact Māori sites, and most of those conducting historical archaeology had received their training in prehistoric archaeology (Smith 1991: 8). During this decade, the New Zealand Archaeological Association began to include historical sites within its site recording scheme (Smith 1991: 8), marking an acknowledgment of the applicability of archaeological techniques to the colonial past. A project in New Zealand that was representative of the emphasis on the study of Māori sites in this decade was the Tongariro Power Development Project (Smith 1991: 8) (Fig. 1).

The predominance of a prehistoric and anthropological background for the emerging discipline of historical archaeology in New Zealand was not mirrored in Australia, where scholars were also drawn from a variety of subject areas such as classical archaeology, history, and geography (Lawrence and Davies 2009: 629). As in New Zealand, a small number of small-scale early studies, primarily driven by historical research but that included elements of archaeological understanding, were undertaken from 1933 up until the 1960s (Paterson and Heath 2009: 113–114). The first substantial, and substantially excavation based, historical archaeological work in Australia was aimed at training postgraduate students in the University of Sydney, the University of Melbourne, and the Australian National University (Lawrence and Davies 2011: 12). Sites excavated as part of this original phase included Port Essington in the Northern Territory and the Irrawang Pottery in New South Wales (Paterson and Heath 2009: 114). The investigations at Irrawang Pottery in the second half of 1969 directed by Judy Birmingham formed a cornerstone of Australian historical archaeology, and industrial archaeology has since been a core focus of Australian historical archaeology (Fig. 2).

The 1970s saw a strengthening of the position of historical archaeology in Australasia, primarily

Australasian Historical Archaeology, Fig. 1 Extensive excavations in Hobart at 15 Hunter Street, Sullivans Cove, showing the areas of excavation, interpretive signage, and nearby inn "The Drunken Admiral" that is of the same era as the excavated site. Historical standing structures, public interpretation, and urban excavation are three key features of Australasian historical archaeology. (Photograph taken by Anthony Jenner and courtesy and copyright of Austral Archaeology Pty Ltd.)

Australasian Historical Archaeology, Fig. 2 Excavation at the Phoenix Foundry in South Australia unexpectedly revealed intact molding floors and large, elaborate casting molds. The footings for cranes that were used to move the molds into place can be seen as the white objects at the top and bottom of the photograph. (Photograph taken by Justin McCarthy and courtesy of and copyright of Austral Archaeology Pty Ltd.)

through the passing of legislation protecting historical heritage and the growth of awareness of the importance of historical heritage among the Australasian public. In Australia, the decade opened with the founding of the Australian Society for Historical Archaeology in 1970 (Lawrence and Davies 2011: 14). Following this, the Hope Inquiry was appointed by the Federal Government in 1972 and 1974 to investigate historical heritage in Australia. It included two archaeologists in its appointments and led to the inclusion of historical archaeological places in the Register of the National Estate (Lawrence and Davies 2011: 13). The Register of the National Estate provided statutory protection for sites throughout Australia, and these inclusions marked the beginning of a series of localized legislative acts across the country aimed at protecting historical heritage. Undergraduate courses in historical archaeology were offered for the first time by Judy Birmingham at Sydney University in 1974. At around this time, the publication of historical archaeology regarding Australian sites widened in scope and increased in quantity. The publications included books, monographs, and articles dealing with site and artifact studies as well as maritime archaeology and heritage management (Paterson and Wilson 2000: 83). In 1977, the first archaeological excavation took place at Port Arthur, an early convict settlement of some size in Tasmania, and this place was to become a testing and training ground for Australian historical archaeology until the present day.

In New Zealand, there was the implementation of the *Historic Places Amendment Act* in 1975, guaranteeing the protection of sites over 100 years old, and the 1976 seminar by the New Zealand Archaeological Association that set out a conscious plan for promoting historical archaeology. Important archaeological studies were also undertaken during this time by Neville Ritchie in the Clutha Valley and Nigel Prickett at Taranaki (Smith 1991: 8). The Clutha Valley project produced the then largest and most detailed historical archaeological study undertaken in New Zealand, and it specifically focused on the archaeological

remnants of the Chinese gold miners associated with the industrial history of the area. This survey marked the first substantial interest in the archaeology of the overseas Chinese in Australasia. Around the same time, Prickett had been investigating the fortifications remaining from the Taranaki wars of the 1860s and 1870s, the first extensive investigation that involved significant amounts of European heritage in New Zealand (Smith 1991: 8). These projects provided important training to the following generation of New Zealand historical archaeologists.

Although the awareness of the value of maritime sites in Australia was growing as a result of activities by amateur divers through the end of the 1960s, it was in the beginning of the 1970s that the first steps toward maritime archaeology were taken in the west of Australia. The practice of maritime archaeology in Australasia arose from the need to successfully manage a number of early Dutch wreck sites along the coast of Western Australia that had become subject to looting and harm (Gibbs 2004: 37). The Western Australian Maritime Museum led the early maritime investigations of the Dutch wrecks, carefully excavating four of them between 1973 and 1976 and displaying cannon, elements of the hull, and cargo from the ship *Batavia* (Lawrence and Davies 2009: 632). The excitement of the history associated with the wreck and the splendor of the cargo significantly raised the public profile of maritime archaeology in Australia. Over the coming decades, while the majority of academics showed considerable apathy in promoting the interests of maritime archaeology, the Western Australian Maritime Museum, in association with James Curtin University, trained the current generation of maritime archaeologists in Australia (Gibbs 2004: 37).

The 1980s saw the growth of consultants working in the private sector practicing historical archaeology in Australia, while in New Zealand, routine funding by the government meant that a considerable number of historical archaeological publications appeared. As an indication of this, over 70% of historical archaeological surveys were conducted for two government bodies: the Forest Survey and Lands and Survey (Smith 1991: 9). The bulk of sites dealt with during this time in New Zealand were industrial, primarily mining, but by the end of the decade, an increase in urban excavation meant that many more domestic sites were also being investigated. The investigation of Māori sites continued to be a staple of New Zealand archaeology through this period, while there was an increase in the investigation of maritime archaeology, beginning in the 1980s (Smith 1991: 9) (Fig. 3).

The situation in Australia was slightly different, as private consultants conducted a large share of the historical archaeological investigations and the foundations for historical archaeology established in academia in the 1970s were consolidated. Graham Connah began teaching historical archaeology at the University of New England in Armidale, and Tim Murray at La Trobe occupied the nation's first position dedicated to historical archaeology (Lawrence and Davies 2011: 14). The "Little Lon" excavation in Melbourne, the Queen's Theatre excavation in Adelaide, and the beginning of excavations in the Rocks in Sydney are examples of extensive urban excavations that began to occur throughout the cities of Australia as the legislation formed in the previous decade was enforced (Lawrence and Davies 2011: 14). Reports published during this time increased in sophistication and attention to detail, especially regarding the artifactual assemblages retrieved as part of the excavation.

The 1990s saw the coalescence of an Australasian historical archaeological consciousness and the formalization of the partnership between Australian and New Zealand archaeologists. This connection across the Tasman Sea had been building for some years since the growth of archaeology in each country. In 1990, the Australian Society for Historical Archaeology held a conference in New Zealand and 2 years later formally changed its name to the Australasian Society for Historical Archaeology, the name of its journal undergoing a similar change. Soon after in 1995, a joint conference was held with the Australian Institute of Maritime Archaeology, which, in 2001, also changed their title to incorporate Australasian. During this time, more appointments were made in Australian universities for positions

Australasian Historical Archaeology, Fig. 3 Precise excavation and recording in progress at Oihi Bay, New Zealand. With a Māori Pa and an early mission station Oihi Bay, it represents a significant contact site. (Photograph courtesy of and copyright of Andrew Blanshard, Department of Conservation, New Zealand)

relating to historical archaeology, and maritime archaeology began to be accepted in the academic establishment. Australia followed New Zealand in investigating Chinese heritage in this decade with a nationwide study (Ritchie 2003: 4). Maritime archaeology also began to lead the way in terms of creating studies with a broad geographical scope, such as the Archaeology of Whaling in Southern Australia and New Zealand project.

The first decade of the twentieth century saw for the first time cohesive trends across Australasia: the continued rise of consultant historical archaeologists in Australasia and a growth of regional projects undertaken by archaeologists in both countries. Scholarly and governmental initiatives, at both regional and national levels, began to concentrate on implementing the digital capture of archaeological data as well as constructing and maintaining historical archaeological databases. Alongside this was a marked increase in the amount of historical excavation in New Zealand (Smith 2004: 257) and a practical concern with the absence of a thorough investigation of the Indigenous Australian colonial past (Harrison 2010: 90). This congruity between historical archaeological practitioners in the two countries has led to a tentative collaboration on practical projects and an even more tentative approach to theoretical issues.

Key Issues/Current Debates

Current debates in Australasian historical archaeology cover a wide range of areas, from the manner that archaeological findings might be communicated to society to ways of understanding and drawing out insight into the working of ethnicity, class, and gender from the archaeological record. Despite the recurrence of the same issues throughout Australasia and a forum for regional discussion, debates still tend to be localized in either Australia or New Zealand with the problems directed toward a national rather than Australasian basis. This mild form of parochialism arises from the value invested in historical archaeology as a tool of nation building as much as it does from the difference in the trajectories of disciplinary development between the countries.

A number of key issues in Australasian historical archaeology are shared between New Zealand and Australia, namely, concerns over a growth of

a large body of unpublished archaeological research, questions about the appropriate scale to conduct studies, possibilities of establishing comparability between sites, and doubts about historical archaeology's role within wider society. Given the difference in the course of development of historical archaeology in the two countries, several critical issues are localized in each country but are still central to current understanding. An example of this is the role of post-contact archaeology in Australia, while in New Zealand, there is a distinct lack of development in the understanding of maritime historical archaeological sites (Carter and Dodd n.d.). The key issue of the appropriate scale that investigations may be conducted at is a core issue in understanding historical archaeology as it relates to the unity of Australasian historical archaeology as a whole.

A consistent issue across Australasia is the high volume of the reports of private consultants that are never offered for publication and therefore are not available to the public or to other archaeologists (Smith 2004; Connah 2007). In both Australia and New Zealand, this growth of unpublished, or gray, literature is often linked with the inability of historical archaeology to communicate its findings to the public. Therefore, this fuels concerns over the place of historical archaeology in wider society. In some ways, it is also seen to hamper the establishment of studies of appropriate scale in Australasia, as essential research that might otherwise be available has been withheld from the grasp of researchers (Connah 2007: 106). This is not always the case as the New Zealand Historic Places Trust maintains a library of thousands of online historical archaeological reports produced by consultants and government departments across Australia make reports available on request. Obversely, the monetary cost of subscription to quality historical archaeological journals or online databases often means that access is prohibited to consultants who are not affiliated with an academic institution.

The lack of explicit theory has often been commented on in Australasian historical archaeology (e.g., Murray 2002) and is often linked to the tension between consultant and academic practices noted above. The most serious attempt to systematically produce and apply a novel theory with a substantial data set thus far has been by Burke (1999) where an analysis of the structural relationship between capitalist ideology and historical architecture is undertaken on a regional basis. A concern with the theory and utility of artifact studies has also been an increasing issue in Australasian historical archaeology, and several papers over the last decade have begun to address the difference between artifact cataloging and artifact analysis (e.g., Crook et al. 2002) or the role of functional categories in analysis itself (Brooks 2005). These artifact studies represent a departure from North American artifactual models and a fast developing independent strand of archaeological theory and method.

The emphasis on post-contact Māori heritage in New Zealand historical archaeology has been continuous, while in Australia, the study of colonial British society eclipsed that of post-contact Indigenous sites in the latter decades of the twentieth century. The recent attention paid to the Indigenous Australian experience of the colonial past, first by Indigenous Australians themselves and more recently by archaeologists, is "transforming the discipline from within" (Harrison 2010: 90). A number of studies have recently been published that reflect a departure from the typical subject matter of Australian historical archaeology and innovations in methods for the archaeological approach to the recent past (e.g., Byrne et al. 2001; Lydon 2009).

Although all these issues touch upon one another, a central problematic that binds most of these issues together is the struggle to introduce a broader scale to the analysis of projects. The comparison of artifact assemblages between sites needs proper frames of reference and coherent analysis, not just cataloging. Critically, as seen in the landmark works of Byrne et al. (2001), Lydon (2009), and Middleton (2008), studies of Australasian contact history benefit enormously from wider contextual studies. The idea of a cultural landscape has severe implications regarding scope and methodological procedure, the issues of which are yet to be completely drawn out. The problems presented by an increasing amount of gray literature leave gaps in the data accessible to larger-scale studies.

Future Directions

The key issues that are of concern to historical archaeologists in Australia and New Zealand have given rise to a number of clear future directions. The broadening of scope of historical archaeological studies to include broader regional spatial and temporal boundaries is one likely future direction. Developments in the understanding of historical assemblages will introduce more nuanced understandings of the meaning that is derived from individual sites. These directions call for broader research frameworks, wide-ranging but not exclusive themes, and more flexible artifact categories. From the early twentieth century, there has also been a growing interest in the practical application, analytical power, and communicative potential of information technology within the subfield.

The improvement of the manner in which historical archaeologists communicate with each other and the public is a necessary direction that must be taken in order to overcome a proliferation of wasted literature. The directions that this is likely to take are twofold: an increased community involvement in archaeological projects themselves and a clearer theoretical understanding of what is of importance to the people that archaeologists engage with. Lessons from contact archaeology will be of particular importance in this regard, for it has introduced a more nuanced and responsive positioning of archaeologists and communities than has previously existed. Therefore, of critical importance to the future of Australasian historical archaeology are openness; engagement with the requirements of regional, national, or local communities; and a growth in the awareness of archaeologists about their current and possible roles in creating the historical past.

Australasian Institute for Maritime Archaeology Inc. (AIMA)

Jennifer F. McKinnon
Program in Maritime Studies, East Carolina University, Greenville, NC, USA
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Information

The Australasian Institute for Maritime Archaeology (AIMA) is an incorporated, not-for-profit organization, dedicated to the preservation of

underwater cultural heritage. Based in Australia, it has sponsored work throughout Australia, Asia, and the Indian and the Pacific Ocean. AIMA's objectives are to support and undertake scientific research within the field of maritime archaeology and to publish the results of this work. AIMA is an incorporated body with a Constitution. All members must agree to abide by the Constitution and its accompanying Code of Ethics upon joining or renewing their membership. AIMA works closely with, and provides advice to, State, Territory, and Australian Federal Government on policy pertaining to underwater cultural heritage, such as the *Historic Shipwrecks Act 1976* and the *UNESCO Convention on the Protection of the Underwater Cultural Heritage 2001*. The URL for AIMA is: http://www.aima-underwater.org.au.

Major Impact

In Australia, AIMA has supported important archaeological investigations on shipwreck sites, including *Batavia* (1629) in Western Australia; HMS *Sirius* wrecked at Norfolk Island; HMS *Pandora* (1791) off far north Queensland; *Sydney Cove* (1797) wrecked in Bass Strait, Tasmania; *Zanoni* (1867) in South Australia; and *City of Launceston* in Victoria (1865). AIMA plays an important role in the dissemination of maritime archaeological research. It has an active publications program, including a quarterly newsletter and an annual journal, the AIMA Bulletin, as well as special publication reports. AIMA also organizes an annual conference and provides scholarship money for members to conduct fieldwork and research.

AIMA plays an active role in international maritime archaeology. The organization strongly supports the *UNESCO Convention on the Protection of the Underwater Cultural Heritage 2001* and is formally accredited by UNESCO as a nongovernment organization member of the Scientific and Technical Advisory Body to the State Parties to the Convention. AIMA also supports the work of the International Committee for Underwater Cultural Heritage (ICUCH) with several of our members represented on the committee and holds an associate membership to the Advisory Council for Underwater Archaeology (ACUA). AIMA members have been involved in training programs in China, Thailand, Taiwan, and Sri Lanka. Joint cooperative projects to assist and support existing or developing maritime archaeological programs have been undertaken in Kenya, Oman, Sri Lanka, Malaysia, Indonesia, Thailand, the Philippines, the Solomon Islands, Korea, and Japan.

AIMA, in conjunction with the Nautical Archaeology Society (NAS – United Kingdom), teaches a four-part course on maritime archaeology. This internationally recognized course is currently run in the United Kingdom, South Africa, Canada, Micronesia, and the USA, among other places. The aim of this course is to introduce the methods and procedures used in maritime archaeology and to generate awareness of underwater cultural heritage preservation in Australia. On completion of each of the courses, students are awarded an AIMA/NAS certificate, which is internationally recognized.

AIMA often lobbies on issues of interest to its membership, such as amendments to underwater cultural heritage legislation in Australia and the region. It has formal ties with other archaeological organizations including the Australasian Society for Historical Archaeology and the Australian Archaeological Association with which it occasionally holds joint conferences.

Australasian Society for Historical Archaeology (ASHA)

Jonathan Prangnell
The University of Queensland, Brisbane, QLD, Australia

Basic Information

The Australasian Society for Historical Archaeology (ASHA) is an organization that represents historical archaeologists from Australia and New Zealand. It is primarily a society for the interchange of ideas and information related to specific sites, regional analyses, and global perspectives of historical archaeology within the archaeological community, the general public, the cultural heritage industry, and the different tiers of government in both countries. ASHA was founded in 1970 as the Australian Society for Historical Archaeology primarily by Sydney-based archaeologists, and it developed out of initiatives by the New South Wales National Trust and the University of Sydney. One of the leaders of this was Judy Birmingham of the University of Sydney (Lawrence 2006: 5) who was the first secretary and later President of ASHA. It held the first of its now annual conferences in Sydney in 1980. Since then, conferences have been held in all parts of Australia and New Zealand, including half way between the two on Norfolk Island. Joint conferences are often held with the Australasian Institute for Maritime Archaeology and occasionally with the Australian Archaeological Association. The ASHA website is at www.asha.org.au.

Major Impact

ASHA has always had an active publication record and has produced a members' newsletter since the beginning of the Association and started producing its journal, *The Australian Journal of Historical Archaeology*, in 1983, under the editorship of Graham Connah. The 1990 conference held in Auckland acted to strengthen the ties between Australian and New Zealand historical archaeologists, leading to the change in the association's name to the Australasian Society for Historical Archaeology. This move was mirrored in a change in the journal's name with the publication of volume 10 in 1992 as *Australasian Historical Archaeology*. ASHA also publishes monographs and landmark doctoral theses in separate publication series.

The ties between historical archaeologists of New Zealand and Australia are more than institutional as both countries share a similar history of British colonization and, for example, an early reliance on mining and pastoral industries, and dependence on the sea for transport, defense, and resources (such as whaling and sealing). Consequently, the research interests of ASHA members from both sides of the Tasman Sea often align. Most of the professional work of ASHA members though does not lie in academe or in museums; most work either in the cultural heritage industry or for the government bodies that regulate that industry. As such, it has always been ASHA's mission to make the results of this consultancy work available to the wider archaeological community and the general public. ASHA also promotes excellence in historical archaeology with an awards program that consists of the annual R. Ian Jack Award for Best Honours Thesis, Judy Birmingham Award for Best Historical Archaeology Consulting Report, Martin Davies Award for Best Public Archaeology Initiative, the biannual Maureen Byrne Award for Best Postgraduate Thesis, the quin-annual Graham Connah Award for Best Publication, and the occasional Ilma Powell Honorary Life Membership Award for Distinguished Service.

Australia and the Origins of Agriculture

Rupert Gerritsen
National Library of Australia, Canberra, ACT, Australia

Introduction

The advent of agriculture as a particular form of food production, along with animal domestication, marks the beginning of an unparalleled transformation in human affairs. The transition that took place, from hunter-gatherers to agriculturalists, underpinned the evolution of a number of great civilizations. Usually the development of agriculture based on rye, wheat, and barley in western Asia, and rice and millet in China, is identified as the archetype for the development of the first pristine agriculturally based societies in human history. Over time extensive investigations in a range of disciplines have been conducted in an endeavor to understand the phenomenon, investigations which have attempted to answer such basic questions as when, where, and how did it happen, and perhaps most importantly, why did it happen at all? More recently, it has been realized that developments in hunter-gather societies were more varied and complex than originally portrayed, and that different pathways and forms of "food production" were conceivable. Accordingly, other patterns of development have come to be recognized, one in particular involving the formation of distinctive, complex, socioeconomic, and sociopolitical structures. Societies exhibiting such characteristics are often labeled as "Complex Hunter-Gatherers" or "Affluent Foragers." However, this phenomenon has made the whole question of the origins of agriculture more complex.

Research into the location and timing of the "agricultural revolution" over the last 100 years or so has resulted in the determination, at least in proximate terms, of when and where such developments took place. In the process, it has become apparent that it was not a discrete event but a circumstance that occurred independently in a number of different places at different times. However, some degree of consensus appears to have been reached in characterizing what happened – that certain groups managed to accomplish, unaided, the transition from hunting and gathering to farming (pristine development), apparently in the space of only a few centuries. The characterization of that transition does depend, however, on the paradigmatic viewpoint. Usually such explanations are framed in anthropological or economic terms, but the process has been described within a biological evolutionary framework.

Agriculture arose independently, or was adopted, at least once on all the inhabited continents, with the reputed exception of Australia. A variety of reasons have been put forward for this apparent anomaly, although it has recently been argued that agriculture was in fact practiced by a limited number of groups in two parts of Australia at the time that British colonization began (Gerritsen 2008). The evidence for relies principally on ethnohistorical and ethnographic information at the moment, rather than archaeology.

Definition

Australia is defined here as the modern political unit, which includes mainland or continental Australia, Tasmania and all offshore islands, and all the islands in Torres Strait, to within a few kilometers of the coast of mainland Papua New Guinea.

The Indigenous population of Australia is usually referred to generically as Indigenous Australians, and this embraces Torres Strait Islanders between the tip of Cape York and the south coast of Papua New Guinea, Aboriginal people of continental Australia, and the Tasmanians. Where Indigenous societies are discussed here, it is in the sense of "traditional" societies, their form at the time when initial contact with Europeans and other outsiders commenced, or began to have a significant influence.

A great variety of definitions of agriculture have been proposed. While it would appear from this that there is little definitional consensus, in

behavioral terms, the principal elements appear to be propagation (sowing, planting, usually of "domesticates"), husbandry (soil preparation, maintenance of moisture and fertility, exclusion of competitors, protection from predators), harvesting, and finally storage. The scale or areal extent of these activities would also appear to be a significant factor, though not always explicitly stated.

Whatever definition of agriculture is considered, all consider deliberate planting as a central activity. One attribute that has been included in definitions of agriculture is the requirement that the crops being grown and harvested are "domesticated." However, this requirement has been widely challenged in recent times (Gerritsen 2008: 29–31). Many, but not all, cultivated food plants appear to undergo morphological [phenotypic] changes and/or speciation, some quite quickly, once they are systematically planted, and in so doing may become human-dependent. But intensive harvesting, without planting, may also produce some of those changes, while plants that are systematically harvested may not undergo genetic changes, which depends on the harvesting method as well as the plant's genetic responsiveness (Gerritsen 2008: 29–31, 38–41, 83–4). Moreover, it is becoming evident that in early agriculture, the crops being grown were wild, "undomesticated," crops. In southwest Asia, current evidence indicates wild, undomesticated or only partially domesticated cereals were being grown well into the Neolithic, the period when it is usually accepted agriculture was becoming, or had become, established (Gerritsen 2008: 31, 41, 74). Rice (*Oryza sativa*) is another case in point. It had been cultivated for at least 3000 years as "ancient cultivated rice," only becoming "domesticated" at the end of the Chinese Middle Neolithic (Gerritsen 2008: 31, 75, 83–4). Some have endeavored to distinguish this period as "pre-domestic agriculture" or "pre-domestic cultivation" (Gerritsen 2008: 30–1). The evidence indicates that initially agriculture took some time to become established as the predominant means of food production and even in the latter part of the Pre-Pottery Neolithic B, from around 9800 cal. BP, hunting, fishing, and wild food procurement (such as nuts and lentils) still provided a substantial proportion of the food supply (Gerritsen 2008: 41).

Although not always explicitly stated, storage or conservation of the yield from crops that are grown is also a central feature of agricultural systems. While physical storage is usually seen in the case of seed, nut, and some tuber crops, it is a frequent practice with vegetatively reproduced staples, such as taro, sweet potatoes, and yams, for the tubers to be left in situ and harvested as needed.

In much of the writings and publications on the origins of agriculture, the term "Neolithic" is treated as almost being synonymous. Broadly speaking, as agriculture, or a mixed economy, such as animal husbandry and agriculture, starts to become the predominant mode of subsistence, permanent habitations, small permanent settlements, much higher levels of sedentism and systematic storage are evident. Although these characteristics emerge from the antecedent period, the Natufian in southwest Asia for example, they are strongly associated with all Neolithic cultures.

Often activities such as clearing, tilling, weeding, fertilizing, watering, and protection of crops are also included in the definition of agriculture. However, there are no systematic studies to support those generalizations and current evidence indicates that at least some may well be much later developments, refinements, or optimization behaviors adopted when agriculture had already become the dominant means of food production.

In summary, agriculture, particular early agriculture, must involve at least propagation (sowing and planting), some husbandry (soil preparation, maintenance of moisture and fertility, exclusion of competitors, protection from predators), harvesting, and finally storage on a significant scale.

Historical Background

The first documented contact Australia had with the outside world took place in March 1606, when a Dutch ship, the *Duyfken*, sailed down and charted 300 km of the western side of Cape York

in Queensland, having contact with some of the Indigenous population, probably the Anggamudi or Wik peoples, as they did. In the following 164 years, most of Australia's coasts were unveiled to the outside world and in 1788, the British established a colony at Port Jackson (Sydney) on the east coast. In the succeeding decades, British colonies were established in many parts of Australia. Where these settlements took hold and expanded the Indigenous population was decimated by massacres, epidemics, loss of land, sources of traditional sustenance, and neglect. One of the justifications used for the expropriation of the continent and the dispossession of the Indigenous inhabitants was the claim that they did not till the land and therefore did not use it productively.

Since that time, evidence has come to light from a variety of sources that Indigenous Australians did plant and sow in traditional circumstances. This includes species of yam (*Dioscorea* spp.) in the Cape York region in Queensland – on east Cape York among the Umpila at Lockhart River and islands offshore, and among the Walmbaria and Mutumi of Flinders Island and the adjacent mainland – and west Cape York among the Wik-Mungkan and possibly the Tjungundji. Planting of yams has also been noted at Kalumburu in the very north of Western Australia. Hynes and Chase reported the Pama Malnkana of northern Queensland planted coconuts (*Cocos nucifera*), while the Uradhi of northern Cape York cultivated the sweet potato (*Ipomoea batatas*) prior to contact with Europeans. Noted Australian poet Dame Mary Gilmore claimed in the 1930s that she had participated in traditional planting of grass seeds, and native fruits such as *quandong* (*Santalum acuminatum*), with Wiradjuri companions as a young girl in central New South Wales in the early 1870s.

A number of other examples have come to light in recent times, often observed by anthropologists and ethnobotanists. The seeds of a perennial herb, *kurumi*, tentatively identified as *Tecticornia arborea*, were carefully scattered in the cracks of the clay pan in the Western Desert of central Western Australia. In 1976, Kimber reported having observed planting in Central Australia of four different species, including two foods – "native fig" (*Ficus* sp.) and *yella* ("bush potato," *Ipomoea costata*). The practice of planting *Ipomoea* spp. has been reported elsewhere in Australia. Ethnobotanist Fiona Walsh also recorded that the Mardu, of the central north of the Western Desert, traditionally broadcast the seeds of "bush tomatoes" (*yalijarra – Solanum diversiflorum*), over burnt ground near their camp prior to rains. In all 19 species have been identified as having been planted by 21 different groups, many as a traditional practice (Gerritsen 2008: 19–23, 58–9) (Fig. 1).

Perhaps the earliest evidence that some Indigenous groups did sow and plant originated with Augustus Gregory, a noted explorer and Surveyor-General of Queensland, who had worked as a young surveyor in Western Australia. He reported in 1886 that in the 1850s, he had observed that the Nhanda of the Victoria District on the central west coast of Western Australia:

> never dug a yam without planting the crown in the same hole so that no diminution of food supply should result (Gregory 1886: 23).

Earlier, the first British explorers, led by Lt. (later Sir) George Grey, to pass through the Victoria District, in April 1839, had come across what appeared to be large yam grounds in the northern part of the Victoria District:

> April 4 1839: And as we wound along the native path my wonder augmented; the path increased in breadth and its beaten appearance, whilst along the side of it we found frequent wells, some of which were ten and twelve feet [3–4 m] deep, and were altogether executed in a superior manner. We now crossed the dry bed of a stream, and from that emerged upon a tract of light fertile soil quite overrun with warran [original emphasis] plants [the yam plant – Dioscorea hastifolia], the root of which is a favourite article of food with the natives. This was the first time we had seen this plant on our journey, and now for three and a half consecutive miles [5.6 kms] traversed a piece of land, literally perforated with holes the natives made to dig this root; indeed we could with difficulty walk across it on that account whilst the tract extended east and west as far as we could see (Grey 1841: 12).

The next day Grey's part encountered what appeared to be permanent settlements of considerable size on the banks of Hutt River:

Australia and the Origins of Agriculture, Fig. 1 Map of the Corners Region, and the location of the Nhanda and Victoria District

> Being unable to ford the river here, we followed it in a SE direction for two miles [3.2 kms], and in this distance passed two native villages, or, as the men termed them, towns – the huts of which they were composed differed from those in the southern districts, in being built, and very nicely plastered over the outside with clay, and clods of turf, so that although now uninhabited they were evidently intended for fixed places of residence (Grey 1841: 19).

As Grey proceeded, he came across other settlements. It would appear that yams were grown in the alluvial river valleys of a series of small rivers running through the Victoria District, such as the Arrowsmith River. Grey noted that "the whole of this valley is an extensive warran ground" (Grey 1841: 54).

The domiciles mentioned by Grey were described in greater detail by other explorers, and appear to have been dome-shaped, constructed with timbers about 15 cm in thickness, 1.8-m high, coated in clay, and capable of easily accommodating 10 or more people. Subsequent research indicated that there were at least four substantial, permanent, settlements in the Victoria District, the largest having had an estimated population of nearly 300, with the occupants evincing a high degree of sedentism (Gerritsen 2000, 2008: 34, 37–8, 77) (Fig. 2).

Based on the definition of agriculture – propagation, husbandry (watering from wells, Gerritsen 2008: 34–5), harvesting and storage (in-ground), of a significant extent – the Nhanda and their southern neighbors, the Amangu, were engaging in agriculture, as well as exhibiting many of the characteristics of a Neolithic society.

The second part of Australia where early agriculture was evolving at the time of contact is termed the "Corners Region," where the corners of New South Wales, South Australia, Queensland, and the Northern Territory meet. This does not appear to have been a unitary phenomenon as the area is generally quite arid. The pattern of development is linked to wide alluvial rivers and lakes, but as the region is drought-prone it was characterized by a "pulsation" pattern of exploitation. Many groups would live, often in settlements with permanent shelters, tethered to permanent watercourses, lagoons, or other water sources until rains fell, or a flood occurred. They would then rapidly disperse to take advantage of the bounty produced as the arid countryside sprang to life, only to retreat again to the more secure supplies of food and water as the country dried out.

Early explorers noted extensive stands of millet or distributions of ngardu in clay pans in numerous parts of the Corners Region. For example, explorer and Survey-General of New South Wales, Major Thomas Livingstone Mitchell, first noted on the lower-central Darling River in 1835 that,

Australia and the Origins of Agriculture, Fig. 2 Site of former village: Hutt River (Gerritsen 2002: 6)

> In the neighbourhood of our camp the grass had been pulled, to a great extent and piled in hay-ricks, so that the aspect of the desert was softened into the agreeable semblance of a hay field . . . we found the ricks or hay cocks extended for miles. . .. All the grass was of one kind, a new species of 'Panicum' related to 'P. effusum' . . . not a spike of it was left in the ground (Mitchell 1839: 237–8).

Similarly, on upper Coopers Creek in south west Queensland, Augustus Gregory had observed in 1864 that the Maiawali or Koa people,

> reap a Panicum grass. Fields of 1,000 acres [400 hectares] are there met with growing this cereal. The natives cut it down by means of stone knives, cutting down the stalk half way, beat out the seed leaving the straw which is often met with in large heaps; they winnow by tossing seed and husk in the air, the wind carrying away the husks (Gregory 1887: 132).

A number of lines of evidence point to the sowing of this grass, *Panicum decompositum*, or its close relatives, known by a variety of Aboriginal names such as *tindil*, *cooly*, and *katoora*. This includes an account of a *katoora* planting ceremony by the Karuwali of southwest Queensland, numerous references in the *Markanjankula* myths of the Wongkanguru to clearing, tilling, and planting of grass seeds and ngardu, and an oral tradition about broadcast seeding of these in the region by an informant of Arabana descent (Gerritsen 2008: 60–1). In this account, a variety of groups in the Corners Region named would:

> chuck a bit there. Not much, you know. Wouldn't be a handful . . . a little bit, spread it you see – one seed there, one seed there, . . . chuck a little bit of dirt on, not too much though. And soon as the first rain comes . . . it will grow then (Kimber 1984: 16).

It would seem that there was a trade in these seeds, carried in specially made bags called *apwa*, weighing up to 23 kg (Gerritsen 2008: 60).

As soon as the British intruded into this region, they noted villages and large population concentrations. For example, on the upper-central Darling River early in February 1829, explorer Captain Charles Sturt reported:

> Early in the day we passed a group of seventy huts, capable of holding twelve to fifteen men each. They appeared to be permanent habitations, and all of them fronted the same point of the compass (Sturt 1833: 89).

Some 16 years later, close to the New South Wales/South Australian border, Sturt again struck upon another village. Composed of boughs and clay, each dwelling had a smaller one attached, as can be seen in a contemporary drawing (Fig. 3).

Some quite large structures were also observed by a number of explorers, some up to 27 m in circumference and capable of accommodating 30–40 people (Gerritsen 2008: 48). In addition, there were frequent references by explorers, surveyors, pioneers, and amateur ethnographers entering the region to "villages" and clusters of dwellings, as being "permanent," "well-built," "substantial," "clay-covered," or "multiroom" (Gerritsen 2008: 47–9, 66–7).

Australia and the Origins of Agriculture, Fig. 3 "Native Village in the Northern Interior" (Sturt 1849: 254)

Population concentrations mentioned by those explorers and the like often reported encounters with groups of many hundreds, sometimes thousands, assembling, congregating, or residing in particular locations (Gerritsen 2008: 50–1). Alas there have been no specific archaeological studies of settlements in the region, although recent archaeological surveys report such things as "flaked stone" covering an area of three square kilometers on the banks of a large waterhole, Lake Idamea, in southwest Queensland and "vast numbers" of surface sites, some with "millions" of artifacts, in the Lake Eyre South region (Gerritsen 2008: 49, 67n327). These higher populations were supported not only by extensive cultivation of *Panic* grasses, ngardu, and "bush onions" (*Cyperus bulbosus*; Gerritsen 2008: 60) and collecting plant-derived foods and hunting, but surprisingly by fish traps, net fishing, and shellfish, as well as net hunting (Gerritsen 2008: 43–6). Analysis, in terms of matching observational and limited archaeological evidence with the known correlates of sedentism, also indicates the people in this region were clearly exhibiting higher levels of sedentism (Gerritsen 2008: 51–5, 63–9, 77–9).

"Direct" or "Proper" storage, as distinct from caching and stockpiling, was also a feature of the Corners Region, many examples have been identified (Gerritsen 2008: 55–8). Stores of grass and other seeds were often observed, packed in 45–50-kg skin bags and clay casings. Edible gum, in "vast quantities" (Sturt 1833: 118–9), fish meal, dried fruits, and many other consumables were also seemingly preserved and stored. The Diyari utilized seed grain pits (Gerritsen 2008: 56), and a drover, Ashwin, came across a Tjingili settlement in 1871, in the north of the Corners Region, with a larger structure in the center where it is estimated about 1 t of grass seeds was stored (Gerritsen 2008: 57). The most likely explanation for the smaller structures associated with the dwellings depicted in Sturt's illustration of a "Native Village" is that these were storage structures (Gerritsen 2008: 57–8).

One of the fundamental changes which appears to take place when a society shifts from hunting and gathering to agriculture is a shift in the division of labor. While archaeological evidence of the division of labor in prehistory is limited, it is consistent with that ethnographically observed in hunter-gatherers, whereby men typically hunt while women collect plant foods and catch small game (Gerritsen 2008: 85–7). In both the Victoria District and the Corners Region, there is evidence of a shift in the division of labor, with men systematically engaging in planting, harvesting, parching, threshing, storing, and even preparing plant foods (Gerritsen 2008: 43, 88–90).

Key Issues/Current Debates

It had been the long-standing consensus that Australian and Tasmanian Aboriginal populations were nomadic hunter-gatherers. Consequently, the issue of why agriculture had not developed or been adopted in continental Australia and Tasmania was the subject of much theorizing and speculation. However, the growing realization that in traditional circumstances Indigenous Australians manipulated the environment in significant ways to enhance its productivity, particular through the use of fire, termed "firestick farming" (Jones 1969), and other forms of intervention, leading to the concept of "domiculture" (Hynes & Chase 1982) began to challenge these preconceptions. In concert with this, a growing body of archaeological evidence has been emerging that "intensification" had been in progress in Australia over the last 5000 years (Lourandos 1997; Gerritsen 2008: 5–15). Evidence of an aquacultural economy, permanent dwellings and settlements, and a higher degree of sedentism in western Victoria also began to emerge in the 1970s. The traditional Aboriginal population here have accordingly been identified as Complex Hunter-Gatherers (Williams 1988), and the region is still under active investigation (Builth 2006; Richards 2011).

Most recently, the proposition that some groups actually practiced agriculture (Gerritsen 2008), and the extent of intervention in the environment, conceptualized as "farms without fences" (Gammage 2011: 281–304), has raised significant conceptual and definitional issues. These have brought to the fore questions concerning the characterization of agriculture, and the distinction between

agricultural systems and the procurement practices of Complex Hunter-Gatherers/Affluent Foragers. Hallam (2011: 125) thus questions whether it is actually "meaningful to separate 'agriculture' as one unitary category throughout space and time?"

The interrelationship between agriculture and sedentism has also brought the issue of sedentism in traditional Indigenous Australian communities into sharp relief. Accounts of seemingly permanent dwellings and settlements, some reportedly quite large, had in the past simply been dismissed or treated as anomalies. The first systematic study of traditional Indigenous architecture by Memmot (2007) has provided a broader perspective, with some discussion on the interpretation of the observational evidence now occurring (e.g., Memmot 2007: xviii, 327, 331; Gerritsen 2011: 36–41).

Undoubtedly the question of agriculture in Australia, and attendant evidence of sedentism, will be a matter of ongoing debate. The debate is, however, likely to be as much about paradigms as about evidence. As can be seen, there has been already been a shift away from the universal characterization of traditional Indigenous culture as simple hunter-gatherers, but what are the alternatives, and can traditional Indigenous societies be described in unitary, generic, terms anyway?

International Perspectives

Since World War II, as information and evidence began to accumulate, a variety of theories on the origins of agriculture were formulated. Braidwood's "hilly flanks" theory focused on population concentrating in the lower Zagros Mountains in the northern Fertile Crescent. Flannery's "edge theory," and Binford's "marginality theory," also saw population concentration as critical, driven by climate change. Explanations based on "population pressure" began with Boserup in 1965 and culminated with Cohen's *The Food Crisis in Prehistory* in 1977. Since that time, many variants of these theories have arisen. Shortly after Cohen published his work, Barbara Bender pioneered the innovative "social competition" class of explanations, an idea taken up by many researchers, particularly by Brian Hayden with his "competitive feasting" model. In the 1980s Ofer Bar-Yosef and his collaborators developed a cultural ecology explanation, the "Levantine Primacy Model," based on the idea that some areas were better favored with domesticable plants and animals than others. An idea first proposed by Darwin in 1868, "weed theories" have been frequently been espoused in the latter half of twentieth century, such as the "dump heap hypothesis" and Smith's "floodplain weed theory." These suggest that humans had inadvertently created habitats for weedy food plants which were then taken into cultivation. Most recently, Gerritsen (2008) has considered the question, with particular reference to Australia, in terms of economic development. This treats agriculture as a form of specialization arising from two factors – higher population densities and innovation rates in areas of higher net natural productivity, and long-term advantageous information acquisition at nodal points in communication, viewed as long-range scale-free networks.

Over the last 11,500 years, agriculture was independently developed in as many as 11 areas outside of Australia (Gerritsen 2008: 141–2). In endeavoring to provide an explanation for the origins of agriculture, the theoretical frameworks or models that have been proposed ought to be able to account for the all the occurrences of agriculture in terms of location and timing, to establish their validity. If the case for agriculture in Australia is supported, then it would provide an excellent opportunity to test those frameworks and models.

Future Directions

As yet there have been no archaeological investigations to directly test the hypothesis that the nominated groups in Australia were indeed engaging in agriculture. The evidence put forward by Gammage also points to the necessity for such studies to more broadly conceive and embrace landscape archaeology more fully. In concert with this, settlement archaeology could be a fruitful field of enquiry. Despite numerous historical

accounts of Indigenous Australians living in permanent structures and settlements, outside of western Victoria (Williams 1988; Gerritsen 2000; Builth 2006), there have been no attempts to investigate such sites. Nevertheless, some recent efforts have focused on field work to at least identify the specific location of some reported settlement sites (Gerritsen 2000, 2002). While such issues could command some attention, given the constraints of limited archaeological resources, in a nation that covers a whole Âcontinent, with a range of other important priorities, progress may well be slow.

Australia, New Zealand, and Papua New Guinea: Museums

Cherrie De Leiuen
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Museums across Australia, Aotearoa New Zealand, and Papua New Guinea are diverse and

exist in a variety of settings. These countries share ancient geographic links and recent histories, yet each has differing cultures and landscapes. The museums of these nations also share a common colonial heritage, but each has different trajectories of development. They range from those which are federally, state, or territory funded, and operate in large cities, to those in small towns, universities, and not-for-profit and volunteer-managed organizations. The nature of their archaeological collections are equally as diverse, but reflect the three principal fields of archaeology undertaken in this region, Indigenous, historic, and maritime. However, the majority of objects held in collections are described as "ethnographic" and are chiefly materials from Indigenous nations across Oceania and Australia, mostly procured in the nineteenth century. There are also collections of archaeological assemblages derived from known contexts, such as excavated material and surface collections.

Undoubtedly, for many archaeologists, museums play the role of a repository for artifacts, kept for future post-excavation exhibition or analysis. To others, museum collections are centers of vast research potential. But more than this, museums are a visible means through which many societies affirm a role for themselves and their relationship to other cultures, to the past and the natural environment. This is not just in the sense of a physical building, but as a metaphor for the construction of a consensus notion of identity and behavior, and a collective memory. Museums in Australia, New Zealand, and Papua New Guinea, like elsewhere, are, however, western constructions and as such can only reflect their societies and the Indigenous cultures within the boundaries from which they have emerged. As such, they are sites of continuing reappraisal and negotiation. They are also sites where archaeological material collected has been used and re-contextualized for purposes of nationalism, to illustrate social history and underscore political narratives, and even reconciliation. They are centers for debate over repatriation, and have moved from the role of collector and classifier to that of advocate and community center.

Definition

The focus of this entry is on museums in Australia, Aotearoa New Zealand, and Papua New Guinea that are engaged in the conservation and exhibition of heritage objects and artifacts, and hold collections of archaeological significance. At the core, they are defined by the frequently cited International Council of Museums (ICOM) definition (2007) as nonprofit, permanent institutions that primarily function to preserve, research, teach, and make objects and information accessible to the public. However, this entry also recognizes that there is a growing shift at the boundaries of what defines museums in this region. For example, a museum may be a keeping place, site, community space, or even a website. This is in part because museums in recent years across Australia, New Zealand, and Papua New Guinea have moved to develop more appropriate relationships with Indigenous communities, and recognize the right of Indigenous authority and control. This has affected the ways in which material is displayed, collected, and repatriated and how new spaces are created. Museums also reflect social change, and are increasingly reliant on new technologies. As such, the definition of a museum is moving from that of a repository to places of knowledge and custodianship, where there need not be any physical evidence of collections at all.

Historical Background

The development of museums in Australia, New Zealand, and Papua New Guinea is inextricably linked to their colonial pasts. At the heart of their foundations lie the philosophies of science, collecting, exploration, exhibition and Empire; hegemonies of primitive, of otherness. They were colonial museums, established by British, white, bourgeois professionals to assert their gentility, and, as MacKenzie (2009: 120) notes, to establish networking opportunities, clubs for like-minded scientific gentlemen and their interests in natural history. The first in Australia, founded in Sydney in 1845, was originally known as the Colonial Museum (now the

Australian Museum) and was followed by the establishment of a plethora of others in the nineteenth century, including the Tasmanian Museum and Art Gallery (1852); the now Museum of Victoria (1854); the South Australian Museum (1861); the Queensland Museum (1862); and the Western Australian Museum (1891). Each colony, and then state, had its own government and its own museum.

The South Australian Museum exemplifies the deliberate exporting of museum as a symbol of a middle class "civilized" society and many of the characteristics of other Australian museums. Adelaide, which is a planned city (as opposed to penal colony), had its museum conceived as part of its original vision. When it was established in 1861, it needed to be filled, and in addition, the bourgeois of Adelaide needed to be on the world map. The exhibitions of "curiosities" were from the many Pacific and other "exotic" cultures. Such "relics" from other cultures became status symbols as discoveries were made on colonial frontiers. Across Australia, collectors were much more interested in obtaining artifacts from the Pacific Islands than Australia, and local Indigenous cultures were undervalued or seen as uninteresting. This legacy is reflected in the collection of most institutions, for example, the Australian Museum collection includes 60,000 artifacts from the South Pacific and 40,000 from Indigenous Australians (see http://australianmuseum.net.au). At the South Australian Museum, displays about Indigenous Australian cultures did not take primacy until as late as the 1990s. In the nineteenth century, such emergent nations saw museums as places to display their identity, history, and conquests; subordinate classes and minorities were excluded by definition. Consequently, to visit a museum was to witness the power of the ruling culture.

In the 1880s, there was a shift to collect the "ethnography" of Aboriginal people, as well as the continued lust for Pacific material. This was in part a reflection of influential individuals and their interests, such as Edward C. Stirling at the South Australian Museum, George French-Angas and Pierson Ramsay at the Australian Museum, and Walter Baldwin-Spencer at the National Museum of Victoria (see MacKenzie 2009). At this time, there was a prevalent belief that Aboriginal people were a "dying race." The focus was on collection, rather than display, before these cultures became "extinct." This led to almost frenzied amassing of cultural material, stolen, looted, and traded from Indigenous communities, much of which was initially exported to the United Kingdom; "For at least the first 60 years of settlement, Australian scientists cheerfully and uncritically dispatched the most interesting specimens to the country most of them still called home" (Anderson and Reeves 1994: 83). In Adelaide, there were many Indigenous people living in the immediate area of the museum, these communities were plundered and then as exploration, rail and missionaries proceeded across the state into what now is the Northern Territory, this collecting continued at rapid pace. The South Australian Museum (like all other state museums) also has a significant collection of human remains (for a discussion see Fforde 2004). In 1956 their then curator boasted that their collection of skulls numbered over 1,000 (MacKenzie 2009: 169). Burial grounds such as that at Swanport, South Australia, were also looted.

The imbalance in power relations between colonizer and colonized is exemplified by this scurry for Indigenous artifacts and human remains and their subsequent trade and commodification. The collecting of Indigenous lithics across Australia commenced in around 1900 in a non-systematic fashion. Collecting tended to focus on highly recognizable stone artifact types, such as axes, grindstones, hammer stones, and on secret/sacred objects such as cylcons and tcheringas. The assemblage from the first formal Australian archaeological excavation undertaken at Ngaut Ngaut in 1927 is located at the South Australian Museum. Museums in Australia, however, failed to recognize the diversity and validity of different Indigenous nations with distinctive cultures and also the antiquity and sacredness of the artifacts they had amassed. This positioned museums as "agent" of the dominant white population and some museums still

continue to hold on to cultural material, including that of a secret and sacred nature.

The origins of museums in Aotearoa New Zealand are not unlike that of Australia. The British Empire unfolded a network of colonial museums across the globe, and associations of scholarly and middle class scientific gentlemen similarly acquired and collected tokens from the "primitive" and the "dying" Maori. Many Maori sites were looted, including burials and sacred places, including marae (Hakiwai 2005). With the Treaty of Waitangi in 1840, there is a defined start date for British rule and the importation of culture. A small museum was first established in Auckland in 1850, then the Colonial Museum was founded in 1865 in Wellington (the first predecessor of the Te Papa Museum); subsequently, the Otago museum in 1868, and Christchurch in 1870 was established (see McCarthy 2011). Ethnographic collecting commenced immediately, in places such as Auckland where Maori populations were dense, and with the New Zealand wars in progress, obtaining cultural items was opportunistic and swift. The myth that the white settlement of New Zealand was more peaceful and civil than other colonies because of the Treaty of Waitangi can be contested by examining its colonial museums. Like Australia, land and cultural appropriation, acquisitions of human remains, and legacies of war and disease are evidenced in museum collections. Observers such as McCarthy (2011) and MacKenzie (2009) both accept the collaboration of some British allied Maori groups in the acquisition of cultural material, even taonga (sacred material) and marae (sacred meeting houses) and their contents. The exhibition "Te Maori" (beginning in 1986) was a watershed for New Zealand museum practice and politics and has been characterized as the beginning of Maori decolonization, "Maori people were taking back control over the representation of their culture" (McCarthy 2011: 54). As a direct result of the "Te Maori" exhibition, Maori communities have subsequently been recognized in cultural protocols and guardianship, and involved in collaboration, consultation, and governance.

Most museums around the world contain at least one mask or other artifact from Papua New Guinea. Enormous numbers of Indigenous artifacts were collected by western scientists, missionaries, traders, and explorers visiting Papua New Guinea during the 1870s and 1880s. In this sense, the history of museums in Papua New Guinea differs – it was a center for material that were taken outside of the country, collected opportunistically and at a frenetic pace to fill museum display cases overseas (particularly Germany) up until World War Two. It was a destination for countless scientific expeditions (Gosden and Knowles 2001) but less for settlement and economic investment. The desire to establish a national museum in this country was comparably late. This may be because there was not a suitable or large enough permanent, middle class, white population to warrant the establishment of such an institution, as local Indigenous populations were not the target audience. Support was initiated by two governors, McGregor and Murray, and resulted in the enactment of the Antiquities Ordinance Act in 1913. Although this legislation showed clear intention to protect Papua New Guinea's cultural heritage for future generations, it was only in 1954 that an Act was passed to provide for the foundation of a public museum. The first National Museum was subsequently established in Port Moresby in 1959. In 1966, the J.K. McCarthy Museum, a branch of the National Museum, was established at Goroka in the Eastern Highlands Province. In 1969, the first Papua New Guinean, Lepani Watson, was appointed to serve on the Board of Trustees. Michael Somare was elected President of the National Museum's Board of Trustees in 1971. Four years later, G.N. Mosuwadoga became the first Papua New Guinean appointed as Director. In 1979, the Museum became officially known as the National Museum and Art Gallery of Papua New Guinea and houses and supports substantive anthropological and archaeological collections and research, "reinforcing an awareness that the culture and lifestyle of Papua New Guinea are as rich as those of any other country" (Wari 1980).

In Australia, the twentieth century also saw the slow rise of a national consciousness and identity. Arguably there is a still a broad lack of interest or

knowledge of Australian history and particularly archaeology, pre- and post-European colonization. However, it was in the latter part of the twentieth century that a second wave of growth in museums occurred and stirred an interest in an Australian heritage. During these decades, new institutions were established, new buildings constructed, and collections increased. The 1960s saw a rapid growth in historical museums, predominately in the regional areas of Australia (Szekeres 2011). However, the dominant narrative presented was of pioneers and settlers, to the exclusion of both "ethnic" and Indigenous people. Change began to occur with the establishment of small museums by groups of post-World War two migrants in an attempt to continue and preserve their own cultural heritage and traditions. For example, the Ukrainian Museum opened in Adelaide in the late 1970s, run by the Ukrainian Women's Association to house their artifacts and archives. Likewise the Polish museum at Polish Hill River in the Clare Valley, where Poles had settled as early as 1838, was opened. These small institutions signify major shifts. The first, particularly among communities of non-Anglo backgrounds, declared that Australia was, in fact, a multicultural nation. It prompted non-Anglo--Australians to want to see themselves and their heritage being represented. Jewish people arrived in Australia along with the British in 1788 on the First Fleet, but where was their story and material culture? It was not until 1982 that the Jewish Museum of Australia opened, followed 2 years later by the opening of the Holocaust Museum in Melbourne. Such a recent establishment is surprising, for Melbourne has the largest number of Jewish Holocaust survivors outside of Israel and the USA. In the same way, Chinese people have a long history of largely unacknowledged settlement in Australia but did not open a museum to tell their stories until 1985.

A second shift to occur in the 1970s was a questioning of gender hierarchies of representation in all aspects of Australian cultural life, including museums. At this time, the androcentric nature of Australian museum culture and displays was also challenged, for until then, the representation of women of all backgrounds and time periods was simply nonexistent (see Anderson 1990; Goodall 1990). A turning point for Australian museums was also the 1975 Piggot Report. This is primarily known for its support and recommendations for a new national museum to be constructed in Canberra, focusing on three themes or galleries: "Aboriginal man in Australia"; "European man in Australia"; and "the Australian environment and its interaction with the two named themes" (Piggot 1975: 71). The Report was also important in putting forward the case to display Aboriginal history across all major museums. Subsequently, the National Museum of Australia Act 1980 was developed and the National Museum of Australia was opened in 2001. The Council of Australian Museum Associations (CAMA) meanwhile developed a policy for museums and Indigenous communities. Previous Possessions, New Obligations (PPNO) was released in 1993, addressed all aspects of museum practice and acknowledged that Indigenous people had primary rights in respect of control and interpretation of their culture (and revised in 2005 as the Continuous Cultures, Ongoing Responsibilities policy document). By the late 1990s, every major museum in Australia had redeveloped its exhibitions of Indigenous cultural material, often in consultation with the communities they sought to represent. Similarly, museum philosophies significantly changed in New Zealand in the 1990s with the adoption of the principal of biculturalism in museums (see Smith 2006; McCarthy 2011). The Museum of New Zealand Te Papa Tongarewa in Wellington was developed on the premise of biculturalism in its construction, management, and organization in an attempt to reconcile its Maori collections with colonial legacies. Since it opened in 1998, "Te Papa" has been popularly supported for its innovativeness in the areas of public access, bicultural history, and Maori authorship. Despite this, Te Papa perhaps still perpetuates an old museum paradigm – Maori cultural material attributed a sense of reverent, static history, while Pakeha (white people) are represented through sometimes superficial blockbuster displays.

Key Issues and Current Debates

It is evident that in museums across Australia, Papua New Guinea, and New Zealand, there have been important improvements made in the portrayal of cultural diversity. Although it is impossible to adjust modern moralities to the past, the message of museums has changed to one that tells the story of the fundamental place of Indigenous nations. Museums are for many, and particularly for tourists, they function as a site of first "contact" with an Indigenous culture. The increased emphasis on engaging and reconciling with Indigenous people has seen, for example, the repatriation of Indigenous human remains and cultural material. But a key issue remains – who are these museums for? Tourism Research Australia's 2009 survey of Cultural and Heritage Tourism in Australia found that international cultural and heritage visitors made up more than half (51%) of all international visitors to Australia in 2009 and, of these, 57% visited a museum. The most recent report by the Australian Bureau of Statistics (2009) estimated that there were 30.7 million annual museum admissions. What is missing from these reports is the percentage of visitors that were, for example, Indigenous Australians, or Vietnamese Australians or Sudanese Australians. The percentage is likely to be small. In museum studies, there have been discourses on global, multicultural, post-colonial, post-modern, and reflexive representation (see Corsane 2005) but in a nutshell, museums *are* western institutions still largely *for* western educated visitors.

The issue of museum visitation is linked to the concept of what is "heritage" in Australia and New Zealand. Although a personally defined concept (see studies by Deakin University 2010 and Aplin 2002), consistently problematic in debates on heritage is that British colonial is what is commonly understood to be meant by the term. Through studying the attitudes of Asian Australians, Clark (2007) found that transnational migrants feel a strong attachment to local and global identities, but a weak attachment to the national identity. Her research found that pride was felt least in Australia's "history" compared to all other achievements and national symbols, such as sport or politics. This may be related to the fact that there were prevalent and legally entrenched racist attitudes toward Asians in Australian up until 1970, but this is not a scenario confined only to Asian Australians. The endorsement of particular cultural symbols by museums, and the larger social and political need to foster a sense of loyalty among migrants from culturally diverse backgrounds through a consensus notion of heritage (see Kofman 2005), which is British, are perhaps more subtle reasons. Szekeres (2011) observed of the National Museum of Australia that its "migration section" was "small, constrained and sometimes misleading and inaccurate." This is not to say that exhibitions should include such a multiplicity of interests as to incorrectly portray historical realities, but simply ones more precisely contextualized.

In Australia, there was also a heritage "movement" in the 1970s, largely focused on the conservation of historic buildings. As a consequence, federal and state legislation that followed saw the beginnings of Cultural Heritage Management and rescue archaeology. Since the 1970s, there has been a large growth in the excavation of archaeological sites across Australia, Papua New Guinea, and New Zealand. As a consequence, there are also a rapidly increasing number of artifacts and collections to be stored and conserved. The curation of the material retrieved from archaeological excavations is most often problematic and a major issue for museums and archaeologists themselves. Schacht (2008) identifies a "curation crisis" in the "inadequate recovery, documentation, and legislative protection of artefacts and in the insufficient resources for their storage, conservation, and management. This has resulted in threats to both the physical condition of excavated collections and their accessibility for research, thus impacting on their research significance." Artifacts recovered mostly make their way to museums, local governments, university laboratories, some with archaeologists themselves. They are a burden on storage and administration, and as pointed out by Robins as early as 1988 (Robins 1988), many archaeologists themselves also contribute to the chaos of museum collections due to an inadequate understanding of the role and

function of a museum, which is not an infinite repository. Excavated material is often of archaeological merit, but of little monetary or aesthetic value. There is little incentive for museums to display such material – mundane, broken, and unremarkable. Most artifacts, once the excavation process is finalized, are not reused or displayed, but lie in boxes separated from context often with dubious documentation and conservation, perhaps with some cataloging. In Australian archaeology, there is greater emphasis on and interest in the process of fieldwork over theory, systems, and landscape over artifacts. There is a low level of training of archaeologists in terms of conservation in the responsibilities toward the collections they create "little recognition of the fact that the organisation, documentation and deposition of collections with a museum is an extension of the process of site management" (Robins 1988: 116).

The only guidelines in Australia to deal with the significance of artifacts are by the Heritage Collections Council of Australia (2001) which provides a framework for the assessment of individual objects, and identifies as primary criteria, historical, aesthetic, and social or spiritual significance but not specifically characteristics of archaeological collections. Schacht (2008) argues that the debate in the archaeological literature has stressed the subjective nature of significance; however, this approach has led to archaeologists rarely identifying any significance of the artifact collections they excavate and manage, and has resulted in the underutilization of the collections in research. An additional issue is the gendered division of labor in this sector. According to data released by the Australian Bureau of Statistics (2009) for the same category of work, women are earning only 63% as much as men. The museum sector also employs a greater number of women than men, and most artifact-based archaeology is undertaken by more women than men.

Across many museums artifacts are often left to speak for themselves in post-modern methods of display and can be ineffective in communicating the more nuanced and complex readings of history and cultural material. This is particularly problematic with artifacts from Indigenous archaeological sites with still hang in an uneasy space in traditional museums. To be able to understand the significance of an archaeologically recovered artifact, the museum visitor needs to have a shift in their understanding and ideas about the past, or a particular culture, and engage with those ideas. This may be easier for most museum visitors attending an exhibition of archaeology from Egypt or Europe – understanding the significance and meaning of a 2,000-year-old sword or necklace is easy and familiar. Viewing and understanding the significance of a 15,000-year-old grindstone or piece of ochre or Indigenous cultural material that is often presented as a bundle of curious, beautiful, unfamiliar objects from an unexplainable, distant past is difficult, unfamiliar, and intangible. Artifacts are often left mute, and for a non-archaeologist, their use or significance (apart from basic observations about function or style, such as in the case of, for example, a boomerang, or a series of 100 boomerangs) is simply elusive. Nor should the contexts be espoused with overt certitude by archaeologists. As pointed out by Stone (2005), archaeologists and curators still have problems in interpreting and displaying material to Indigenous people, but there are also issues in providing meaning to a broad public, a matter that can only be addressed by broader changes in terms of education and perceptions of the significance of the archaeology of Australia, as well as Papua New Guinea and New Zealand.

International Perspectives

The most significant and contested issue for museums in Australia, New Zealand, and Papua New Guinea, which has the greatest impacts on institutions internationally, is undoubtedly repatriation. The past 30 years has seen the emergence and growth of this issue, for the reason that there are likely to be thousands of human remains and sacred items scattered across museums from the United Kingdom and Germany to France and the United States of America. Human and cultural material was procured, acquired, looted, or stolen up until the 1930s (see Fforde 2004). The issue is driven by Indigenous communities and is largely

dependent on the development of goodwill between the traditional owners, governments, and museums. In most cases, it involves lobbying overseas governments and institutions on the cultural significance of repatriation, and is supported by federal governments in Australia, New Zealand, and Papua New Guinea. Although most overseas institutions would argue that there is scientific value in continuing to research human remains, what little research has been undertaken was done without the permission of descendent communities. The retention of human remains by museums in Europe and North America against the wishes of claimants is perceived as a continuance of colonial oppression (Hubert and Fforde 2005: 111). Many institutions perpetuate a discourse of ownership, a perceived duty to retain an inheritance from the past for a research future, which is effectively a denial or devaluing of alternative cultural meaning.

In terms of Australian museums, repatriation is managed by eight collecting institutions and assistance is provided where necessary by the National Museum of Australia and/or the relevant major state or territory museums to the federal Indigenous Repatriation Program, including research to establish the provenance of ancestral remains and the identification of overseas collections of ancestral remains and the holding of remains in temporary "keeping places." There have been over 1,000 repatriations to communities in Australia since 2000. Since 2003, New Zealand authorities have followed a policy of facilitating the repatriation of Māori ancestral remains from museums around the world (see Hole 2007). To date, Te Papa and its predecessor, the National Museum, has repatriated ancestral remains from twelve countries bringing home close to 322 skeletal remains and estimates that there are over 500 still awaiting return.

Future Directions

The presentation and recognition of the archaeology of Australia, New Zealand, and Papua New Guinea and the contribution that museums can make to this process is yet to be fully realized. The attitude and perhaps ignorance to the archaeology that occurs daily is probably best summed up by a question asked by an ABC journalist of TV host Tony Robinson of "Time Team" fame in when on a recent visit to Australia to promote his book on Australian history:

> In the Time Team series you're unearthing stuff that dates back as far as the Iron Age. Of course, Australia is a much younger country, and I wonder whether lack of brevity of history doesn't make for boredom to a certain extent?. (Ali Moore, Lateline 21/11/2011)

Of course, the answer given was that Australia has some of the world's oldest archaeology, some more than 50,000 years old. The fault lies here with archaeologists, museum professionals, and education sectors in the failure to communicate broadly the meaning and nature of archaeology of this region, and that our own archaeology is not taught in schools. Museums have tended to focus on collections and exhibitions rather than on other aspects of museums' policies and programs such as education, community engagement, and public programs, as well as engagement with archaeologists. This is also linked to the fact that museum education programs have traditionally been oriented to supporting school curricula, and archaeology as part of the school curricula is yet to be realized. Perhaps future generations, educated with an understanding of their own regional archaeologies, will be able to comprehend the significance of a flake and a core just as well as a coin or hatchet.

Online access to collections complements such a change to both education and public programs. Many museum objects can be already be viewed online, for example, the Collections Australia Network is part of the Federated Open Search Project where it is possible to search the online collections of the Powerhouse Museum, Museum Victoria, National Museum of Australia, Picture Australia, NSW State Records and Libraries Australia via their website. There were 51.5 million unique online visits to Australian museums with a total of 127.3 million web pages viewed in 2007–08 (ABS). With increased access to the internet, better and continuously evolving technologies, online collections are certainly the

future for museums. Changes in architecture have already taken place as a response to the changing role of the museum as a cultural center, rather than a repository for objects, such as Bunjilaka at the Melbourne Museum. Indeed, objects and collections may not be an essential focus of museums of the future.

Museums have traditionally conserved and classified, interpreted, and exhibited. The shift has already begun from the role of a classifier to one of advocate – in terms of social critique and the repatriation process. There is a shift in the role as custodian to one of stewardship, from preservation to one of cultural maintenance. Authority and authorial voices remain very important in this debate, especially in the context of collections that are archaeological or ethnographic in nature. Perhaps museums of the future may not be staffed with primarily white, tertiary educated professionals, but a workforce that is more reflective of the collections they hold and audiences they engage with. Positive change and development can also occur with proactive and genuine community collaboration and interaction, be it with Indigenous communities or archaeologists that may result in enduring, valued, and meaningful museums.

Australia: Cultural Heritage Management Education

Heather Burke
Archaeology, Flinders University, Adelaide, SA, Australia

Cultural heritage management (CHM) education is a vital component in managing cultural heritage resources, since it produces each new generation of professionals who work across its many allied fields. In Australia, as in other countries, CHM encompasses a wide range of specialist subfields, from built heritage (conservation or landscape architecture), materials conservation, and heritage planning to museum studies, Indigenous heritage, archaeology, and professional history. This mosaic has created a complex system of educational opportunities for those seeking professional qualifications to practice and has also created its own particular suite of problems.

While such breadth is partly a strength, in that there are many formal and informal options for education across all sectors of the population, it is also a weakness, in that the field is highly fragmented, with few opportunities for coordination or collaboration, and a clear need for benchmarking, quality standards, and a national outlook on tackling educational and skills needs. One recent study identified this fragmentation as the key problem preventing the sector from responding effectively to regional skills shortages, emerging priorities for skills development, or contributing to nationally significant research agendas and cultural and environmental challenges (Ireland et al. 2013). No enforceable professional standards or national accreditation relating to heritage education and training currently exists in Australia.

Current routes for CHM education in Australia follow a variety of formal and informal pathways. Formal paths are the various degrees, diplomas, or certificates offered through universities or colleges of technical and further education (TAFEs). Informal mechanisms are usually offered through various not-for-profit cultural heritage organizations (such as museums, the National Trust, or Conservation Volunteers Australia) or non-government statutory bodies, such as the Historic Houses Trust of NSW or the Port Arthur Historic Site Management Authority. Informal training mechanisms usually aim to encourage a more general "culture of care" around heritage through educating the public in the conservation of heritage places, creating greater knowledge of heritage management issues, or changing visitor behavior at heritage sites.

Formal Cultural Heritage Management Education in Australia

Australian higher education has traditionally been split across the university and TAFE sectors, with TAFEs being viewed as vocational (the government language for the training they offer is known as Vocational Education and Training, or VET), rather than academic. The gap between the two sectors is perhaps most clearly measured by the

forms that heritage education within each typically takes. Heritage as offered through a TAFE College is typically only available as a module within a larger course on tourism, Aboriginal languages, guiding, or land management and conservation. The exceptions to this are more tailored courses in Indigenous heritage management designed by some universities and offered in conjunction with state government partners, usually in response to legislative changes that require particular skills. Heritage trades (i.e., stone masonry, thatching, traditional joinery or carpentry, and other craft-based skills) are also only available through TAFE or through a traditional apprenticeship system (although only 2% of apprentices learn heritage skills in this way; Godden Mackay Logan 2010: 16). Current literature, however, points to such trades being in chronic shortage, due to the disappearing knowledge of heritage crafts, the advancing age of knowledgeable tradesmen, and the lack of incentives for them to take on new apprentices. There are thus very few opportunities to pass on existing heritage trade knowledge and skills (Godden Mackay Logan 2010: 15–16).

At universities the traditional path remains a 3-year undergraduate plus 1-year honors degree (usually a combination of coursework and thesis), although this, too, has been challenged in recent times. Major changes to the Australian education sector in the 1980s and overall increases in the proportion of the population seeking a higher degree qualification resulted in more students studying at tertiary institutions and created broader scope for vocational courses in heritage to be introduced (Beck and Balme 2005:32). Through the 1990s, changes happening outside the academy became relevant in driving a demand for CHM employment, creating increased demand for more and better skilled graduates, and transforming the CHM education landscape in the process. The importance of native title-related work after the introduction of the Native Title Act 1993 (see also McNiven, this volume), urban expansion in southeastern Australia, and the mining boom in Western Australia saw the numbers employed in the heritage sector grow substantially throughout the late 2000s and early 2010s, leading some universities to try and address the former divergence between the training offered in a degree, the vocational training offered by TAFE, and apprenticeship-style opportunities to learn "on the job."

This is most obvious in developments around graduate coursework programs related to various aspects of professional archaeological and heritage practice. In 2005 a national survey of archaeologists identified a need for a vocationally oriented fourth year option (i.e., a graduate diploma) that was different to the traditional research-oriented honors year. While isolated attempts to create graduate diploma degrees in heritage date back to the 1980s, several universities responded more successfully to recent needs by developing vocationally oriented options that mix formal, informal, and "on-the-job" aspects of training. Recently, several universities have also become dual-sector institutions (i.e., both universities and TAFEs), allowing them to offer both degrees and VET training.

Informal Cultural Heritage Management Education in Australia

Raising public awareness of heritage as an important issue in Australian society is also an important heritage education goal. Public interest in heritage generally, and in some of the particular disciplines that study heritage, such as archaeology, is directly related to the social basis for cultural heritage management, since the key to successful heritage management lies in collaborative work with communities, traditional owners, and other stakeholders. The two are combined most often through interpretive works on or about a site or public archaeology programs ("education through experience") built into the process or the outcomes of cultural heritage management work, including open days, public site visits, and tours (see also Ryzewski and Carman, this volume).

Large urban excavations in the 1990s at The Rocks in Sydney and Little Lonsdale Street in Melbourne, for example, both engaged

hundreds of volunteers in public archaeological activities and education as part of the development work at these sites. The best long-term outcome of such projects is probably The Big Dig Archaeology Education Centre in The Rocks, which was purpose-built to provide an ongoing range of educational experiences in archaeology and the heritage of Sydney. Many other projects lead to smaller, more site specific, but no less valuable, informal educational outcomes, such as options for interpretation of particular sites.

In NSW the public basis for CHM and resulting tools for public outreach have been codified more strongly through historic site legislation that often requires the incorporation of public education facets into cultural heritage management plans, especially for state-significant historical archaeological sites. The work of the Heritage Branch of NSW has been devoted to promoting public awareness by building various promotional mechanisms to standard archaeological and other consultancies.

The variety of, need for, and sustained interest in cultural heritage management educational opportunities across Australia hold great potential for the future of managing cultural heritage resources. Creating better links between universities, TAFEs, community organizations, and volunteer and vocational sectors will bring the disparate facets of CHM education closer together and mend some of the rifts that currently fragment it.

Australia: Domestic Archaeological and Heritage Management Law

Sharon Veale
Godden Mackay Logan Heritage Consultants, Redfern, Sydney, NSW, Australia

Introduction

Heritage law in Australia is dynamic and challenging. It is closely connected to the broader framework of environmental planning, protection, and regulation. Australia's first heritage management legislation dates from the 1970s. It was enacted in response to the widespread public concern regarding the destruction and loss of many important natural and cultural places as the Australian urban landscape rapidly modernized during the 1960s and 1970s. Since that time, the theory, practice, and public interest in natural and cultural heritage conservation has changed considerably. It has evolved from an ad hoc

community-driven movement focused on saving natural environments, historic places, and buildings through activism and protest to an increasingly complex multilevel system of heritage laws and procedures.

Australia has a federal system of governance. It is comprised of the Commonwealth, six states, and two mainland territories, each of which has its own statutes for heritage management. Urban planning, development, and heritage conservation are considered matters of interest to the states (Logan 2007). Yet, the demarcation of roles and responsibilities between the Commonwealth and the states and territories has been the subject of ongoing debate and review in many areas, including heritage management (Aplin 2002). The Council of the Australian Government Heads of Agreement for the Commonwealth and State Roles and Responsibilities for the Environment established a three-tier system for the management of heritage in Australia in 1997. As part of that Agreement, responsibility for listing, conserving, and managing heritage of national, state, and local significance is delegated to the Commonwealth, the states and territories, and local governments, respectively (Productivity Commission 2006).

The multilevel system of heritage law is administered by various agencies and authorities and requires adherence to heritage conventions, charters, codes, manuals, and standards of practice that are primarily executed and evaluated by tertiary-educated heritage professionals and specialists. Reflecting the unique qualities and diversity of Australia's heritage, the legislative framework protects natural heritage, Aboriginal and Torres Strait Islander heritage (Indigenous), historic places, archaeology, historic shipwrecks, and industrial and movable heritage.

Definition

In recent years, understandings of what constitutes heritage in Australia have been influenced by increasing ethnic and cultural diversity, shifting public attitudes and broader trends in the field. As such, defining heritage and what it comprises is the subject of ongoing debate and refinement (Conroy 2007). Implementing new legislation is a significant practical undertaking and given the dynamic context, it is often difficult to ensure that heritage law reflects current definitions and community values.

Notwithstanding the energetic efforts of the National Trusts in the postwar period, in Australia, heritage came to political prominence through the concept of the National Estate. The "National Estate" was first coined in Australia by Prime Minister Gough Whitlam in 1972, following the example of the American President, John F. Kennedy (Veale et al. 2012). Initially, there was some imprecision in the use of the term, but by 1974 and the release of the *Report of National Estate*, it was defined as comprising the *natural and cultural environment, archaeological and scientific areas and cultural property which are of outstanding significance to the World, to the Nation or of aesthetic, historical, scientific, social, cultural, ecological or other special value to any part of the nation, including a region or locality that should be conserved, managed and presented for the benefit of the community* (Hope 1974).

In 1979, *The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance* (the Burra Charter) was adopted. The Burra Charter established a series of best-practice conservation principles and processes that are underpinned by the central concept of cultural significance. Reflecting the definition of the National Estate, under Article 1.2 of the Burra Charter, cultural significance is defined as aesthetic, historic, scientific, social, or spiritual value for past, present, or future generations. Cultural significance is embodied in the place itself, its fabric, setting, use, associations, meanings, records, related places, and related objects which may have a range of meanings for individuals and groups (Australia ICOMOS 1999). While the Charter has not been officially adopted in legislation, its principles and processes are evident in heritage management law throughout Australia.

Notwithstanding the influence of the Commonwealth and the Burra Charter, variation in the definitions used in Australian heritage law persists. These variations provide an indication as to what defines heritage in each jurisdiction.

In most instances, legislation defines and protects Indigenous and non-Aboriginal (historic) places and objects separately. Typically, "heritage" is not specifically defined in the legislation; rather, a series of criteria are used to assess whether a place or item has sufficient cultural value or significance to be protected at local, state and territory, Commonwealth, or national levels. For example, the Heritage Acts in South Australia (SA), Victoria (Vic), Queensland (Qld), Tasmania, and Western Australia (WA) specify a place is of heritage significance if it can be demonstrated to satisfy one or more heritage criteria. Under the New South Wales (NSW) *Heritage Act 1977*, items of environmental heritage are protected. This definition includes natural places, as does the Australian Capital Territory's (ACT) *Heritage Act 2004*, which protects places of natural or cultural significance (Boer and Wiffen 2006). The *Heritage Conservation Act 1991* (Northern Territory NT) includes places and objects of social, aesthetic, or scientific value and may include geology, fossils, archaeology, objects, buildings, precincts, works, relics, gardens, coastlines, landscapes, and ruins the *Heritage Act 1993* (SA) conserves places of cultural value, including places of geological and palaeontological significance.

Generally in Australian heritage law, a distinction is made between heritage places and archaelogical objects and relics. Specific provisions to protect objects and relics are included in most heritage acts in Australia. Historic shipwrecks are defined as a special type of object which are protected by State and Territory legislation in conjunction with the Commonwealth *Historic Shipwrecks Act 1976* which protects wrecks and associated relics that are 75 years or older.

The *Victorian Heritage Act 1995* protects places and objects of significance to the State (excluding Aboriginal heritage). Under that Act, an archaeological relic is defined as any archaeological deposit; artifact, remains, or material evidence related to non-Aboriginal occupation that is 50 or more years old (*Victorian Heritage Act 1995* Section 3). Similarly, in NSW, under the *Heritage Act 1977*(NSW), a relic is any deposit, artifact, object, or material evidence that relates to the settlement of NSW not being Aboriginal settlement and is of State or local heritage significance (*Heritage Act 1977*). Until amended in 2001, the *National Parks and Wildlife Act 1974* also included provisions for the protection of relics, however, in that statute relics related to Aboriginal occupation. Unlike Victoria and NSW, in WA, under the *Heritage of Western Australia Act 1990* and the SA *Heritage Act 1993*, archaeological relics are not referred to, though in WA regard may be given to archaeological value when a place is being considered for entry onto the Register. In SA, a place of archaeological significance may be registered, and a permit is required to remove cultural artifacts from such places.

Across Australia, Indigenous heritage is variously defined. The definitions tend to reflect the different approaches that emerged when Indigenous heritage law was initially passed in the 1970s. In Northern Australia emphasis is placed on the protection of sacred sites and includes any land that is sacred to Aboriginal people or of significance according to Aboriginal tradition. Conversely, across Southern Australia, Indigenous heritage legislation was defined by reference to material evidence (relics or objects) related to Aboriginal occupation such stone artifacts, campsites, and hearths. For example, under the *Aboriginal Relics Act 1975*, Tasmania, a relic is defined as the physical remains of past Aboriginal occupation prior to 1876 and can include middens, stone arrangements, engravings, and rock art. Most definitions for relics and objects exclude those made for the purpose of sale. The assessment and protection of these types of evidence was and is still largely managed by archaeologists, whereas assessments in Northern Australia are predominately undertaken by anthropologists (Office of Environment and Heritage 2012). In NSW, under the *National Parks and Wildlife Act 1974*, Aboriginal objects and Aboriginal places of significance to Aboriginal people are protected. An Aboriginal place is defined in the Act as being a place that, in the opinion of the Minister, is or was of special significance with respect to Aboriginal culture (Section 84 NPW Act 1974 (NSW)) *National Parks and Wildlife Act 1974*.

Historical Background

In Australia, heritage management law has had a relatively short history when compared to countries overseas. Despite this, heritage law and the periodic reforms demonstrate how the theory and practice of conservation has evolved and how major trends, public and private attitudes, interests, and pressures have been interpreted and applied to the legal framework for the identification, management, and protection of significant heritage places, objects and relics.

Heritage Legislation: Australian States and Territories

One of the earliest pieces of heritage legislation, the *Native and Historic Objects Heritage Protection Ordinance* was passed in 1955 in the NT (North 2006). Elsewhere, in NSW, the *Crown Lands Consolidation Act 1913* included provisions for the establishment of reserves to protect Aboriginal art sites. Some years later, amendments to the *Local Government Act* in 1945 included provision for places or objects of historical or scientific interest to be preserved (NSW Heritage Office 2000). Yet across Australia, most heritage law dates from the 1970s and reflects the political response to the community's growing concerns about the destruction and loss of the historic and natural environment. The table below lists the main federal and state and territory heritage and related statutes in force at the time of writing (Table 1).

In 1974, Victoria led the other states and territories when the *Historic Buildings Preservation Act 1974*, which focused on protecting buildings of historic or architectural significance, was enacted. NSW had passed the *National Parks and Wildlife Act* (NPW Act) in 1967, the same year that the *Aboriginal and Historic Relics Preservation Act 1965 (SA)* came into force. Reflecting the American legislative model, the *NPW Act 1967* established the National Parks Service and a formal mechanism for the reservation of National Parks, State Parks, and Historic Sites; which were areas comprising buildings, objects, monuments, or events of national significance. In 1969, significant amendments were made to the

NPW Act, and the objectives for cultural heritage broadened to include the conservation of objects, places, or features (including biological diversity) of cultural value within the landscape, including places, relics, and features of significance to Aboriginal people, and places of social value to the people of NSW, and places of historic, architectural, or scientific significance. Amendments to the *NPW Act* in 1974 created provisions for the gazettal of Aboriginal places which affords protection to places of cultural significance regardless of whether objects are present.

In NSW, with the passing of the *Heritage Act 1977* (NSW) and the *Environmental Planning and Assessment Act 1979 (NSW)*, heritage protection became part of an integrated system of planning and environmental management. Some states took considerably longer to legislate for heritage protection, most notably Qld and WA. Both states passed legislation almost a decade later than NSW due to the lack of political will and the economic power of the mining industry (Spearitt 2012). Tasmania, with its tangible convict heritage, was without formal heritage protection until 1995, yet with negligible urban development and growth, there was no imminent threat to heritage places. The first wave of legislation passed during the 1970s tended to focus on historic heritage, natural heritage was generally protected through national parks and reserves, Aboriginal heritage was afforded blanket protection, and consideration of movable heritage objects was typically overlooked (Marshall 2010).

The legislative mechanisms and regulations for heritage management in Australia play a crucial and central role in the management of Australia's heritage at local, state and territory, and national levels. In all jurisdictions, similar legislative and administrative systems have been established. While the extent to which heritage is managed and regulated under each act varies, essentially four main types of legislation are apparent (Pearson and Sullivan 1995). Firstly, there are acts that separately protect Indigenous and historic sites including cultural places, heritage, sites, and relics. Secondly, a number of acts manage heritage through land or site management. Examples include forestry, national parks, or historic houses legislation that typically includes provision for the conservation of heritage within the estate they manage. The *Historic Houses Act 1980* (NSW) provides for the care, control, and management of historic houses, and other buildings of historic importance is an example. One of the oldest acts of this type still in force is the *Newstead House Trust Act 1939* (Qld), which establishes a board of trustees for the Newstead House and for the conservation, education, enjoyment, and public access to Brisbane's oldest residence. Thirdly, land use planning legislation in most states and territories includes specific provisions that regulate development with regard to places of environmental heritage value. Finally, some acts such as the National Trust Acts establish the Trusts in each state and territory and provide for the preservation, maintenance of places of historical, artistic, and scientific interest and the compilation of registers of heritage places.

With regard to historic heritage legislation such as the *Heritage Act 1977* (NSW), *Heritage of Western Australia Act 1990* (WA), *Heritage Conservation Act 1991* (Northern Territory NT), *Queensland Heritage Act 1992* (Qld), *Heritage Act 1993* (SA), *Heritage Act 1995* (Vic), the *Historic Cultural Heritage Act 1995* (Tas), and the *Heritage Act 2004* (ACT), the objectives typically comprise maintaining and managing a heritage register, the establishment of a heritage council to provide advice to government, manage statutory listings, and review proposed changes to listed items; regulation and control over development affecting listed places, the preparation of guidelines, and standards for heritage practice; assistance with the provision of heritage advisory services to local councils; and funding to assist individuals and communities with the costs of conserving heritage.

It is in the area of Aboriginal and Torres Strait Islander heritage law that there is considerable variation between jurisdictions. NSW was the second government in Australia to enact legislation to protect Aboriginal heritage. Under the *NPW Act 1974* (NSW), it is an offence to harm an Aboriginal object or Aboriginal place. When the Act was passed, there was no requirement for Aboriginal people to be involved in determining

or protecting their heritage. Recent changes such as the guidelines for Aboriginal consultation and the approaches mooted as part of the Aboriginal heritage law reform place much greater emphasis on Aboriginal involvement. This shift is apparent in other states and territories and reflects a heightened awareness of Australia's obligations under the 2007 United Nations Declaration of the Rights of Indigenous People, combined with the ongoing determination and advocacy of Aboriginal people to identify and conserve their heritage.

In South Australia, the *Aboriginal Heritage Act 1988* is the third such act in as many decades. It provides for the conservation of Aboriginal heritage through blanket protection for Aboriginal sites, objects, and remains. The Act provides for an Aboriginal Advisory Committee which goes some way toward recognizing the rights and role of Aboriginal people in heritage protection. The Act is currently under review, its effectiveness having been undermined by unsuitable administrative policies and procedures, alongside political and public apathy (Whiltshire and Wallis 2008). Principles that are part of the legislative review in SA, including the recognition of Aboriginal custodianship and enabling Aboriginal people to negotiate heritage agreements, indicate the current provisions related to Aboriginal involvement are outdated, particularly given the influence of the *Native Title Act 1992* (Cwlth) on heritage protection. In WA, the *Aboriginal Heritage Act 1972* is the primary statute protecting Aboriginal cultural heritage. It provides blanket protection for places and objects customarily used by or traditional to the original inhabitants of Australia or their descendants. The Act is currently under review and is widely regarded as having proved ineffective in protecting Aboriginal heritage. By contrast, in Victoria, the *Aboriginal Heritage Act 2006* has generally enhanced the protection of Aboriginal cultural heritage, provided greater certainty in the context of development and improved Aboriginal engagement in the process. The "efficacy and efficiency" of this Act is currently under review focused on a number of operational and substantive issues including the integration of cultural heritage management with land use planning, according respect and status to Aboriginal people, and penalties and enforcement (Department of Planning and Community Development 2012).

Federal Heritage Legislation

In 1973, Australia ratified the UNESCO World Heritage Convention, only the sixth nation to do so. This initiative, combined with the policy objective of the Whitlam Federal Labor Government from 1972 to 1975 to preserve and enhance the quality of the National Estate, established the fundamentals of the Australian heritage system. The 1974 Committee of Inquiry into National Estate, chaired by R. M. Hope (Hope Inquiry), helped define the concept of the National Estate which was eloquently summarized by the Tasmanian Premier, as the "the things we want to keep" (Australian Government Publishing Service 1974). The *Australian Heritage Commission Act 1975* was a key recommendation of the Hope Inquiry and the first Act of Parliament to protect heritage at Commonwealth level. The Act created the Australian Heritage Commission with responsibility for the identification, promotion, and conservation of Australia's National Estate and established the Register of the National Estate (RNE) an inventory of Australia's natural, historic, Aboriginal and Torres Strait Islander heritage which has special value for present and future generations. Aside from the lists of heritage places assembled by the various chapters of the National Trust, the RNE was Australia's first national heritage list included natural, Indigenous, and historic places. Any person was able to nominate a place for the Register. It reflected the community-driven, inclusive view of heritage that was a feature of the progressive new nationalism of the Labor Party under Gough Whitlam (Davison and McConville 1991).

Characterized by an ambitious political and social agenda, this period was arguably the highpoint for Australian heritage conservation. Similarly, the focus on Indigenous affairs intensified during this time, resulting in significant changes to legislation and policy at both federal and state levels. The *Commonwealth Aboriginal Land Rights (Northern Territory) Act 1976*, the *Aboriginal Heritage Protection Act 1972* (WA), and the *Northern Territory Aboriginal Sacred*

Sites Ordinance 1978 were passed. And while the Australian Heritage Commission's work on the Aboriginal National Estate was "tentative and slow," the understanding and appreciation of Indigenous cultural heritage burgeoned (Commonwealth of Australia 1985). The *Indigenous and Torres Strait Islander Act 1984* (Commonwealth) passed a decade later reflected just how far the understanding of Aboriginal issues had come, particularly, how past dispossession and dispersal of the Aboriginal and Torres Strait Islander peoples and their present disadvantaged position in Australian society had impacted on Indigenous people. Under the Act, Indigenous people may apply to the Federal Minister for Environment to make a protective order over areas of significance where those areas are under threat of damage or destruction.

Since 1996, much of the political largess of the Whitlam Labor years has been eroded at federal level despite significant legislative and administrative reforms. The *Environment Protection Biodiversity and Conservation Act 1999* (EPBC Act) which repealed the AHC Act and the *World Heritage Places Conservation Act 1983* is the Commonwealth's principle heritage law. The EPBC Act (s. 528) defines "heritage value" as the place's natural and cultural environment having aesthetic, historic, or social significance, or other significance, for current and future generations of Australians. Included in the Act's objectives are the promotion and conservation of biodiversity, the protection and conservation of heritage, and assisting with the implementation of Australia's international environmental responsibilities such as those under the World Heritage Convention. Under the EPBC Act, Commonwealth environmental assessment processes are triggered by matters of national environmental significance. Such matters include the likely significant impact on world heritage values or any significant impact on the national heritage values of a place on the National Heritage List (NHL). Amendments to the EPBC Act in 2003 created the NHL and the Commonwealth Heritage List (CHL) and in so doing clarified that the role of the Commonwealth is to protect places of outstanding significance to the nation and places on Commonwealth-owned and administered land that are of significance. Following these changes to the EPBC Act, the Australian Heritage Council was established under the *Australian Heritage Council Act 2003*. This Council replaced the Australian Heritage Commission.

While strengthening the protective mechanisms for National and Commonwealth heritage, the EPBC Act simultaneously narrowed it. Under the concept of the National Estate, heritage was broad, community driven, and inclusive. At its height, the Register of the National Estate (RNE) included 13,000 places. Since the amendments creating the NHL and CHL were passed in 2003, fewer than 500 places have been listed on the NHL and CHL, a fraction of total number of places listed on the RNE. Led by the federal government, reform of Australia's national environmental law is underway. Reforms and reviews to other heritage statues, especially in the area of Indigenous heritage law are currently in progress in NSW, Western Australia, Victoria, and South Australia.

In the wake of funding cuts, sweeping public sector realignments and the prevalent view that heritage is a cost burden for owners and developers requiring complex assessment and approvals processes, the future of heritage protection law in Australia is uncertain.

Key Issues/Current Debates

Presently, there are a series of challenging issues and debates influencing heritage law and conservation practice in Australia. Climate change, environmental sustainability, urban development, mining, and economic growth in the context of global economic uncertainty and a lack of bipartisan government leadership on heritage have had an impact on heritage management and protection.

Current reforms to both Indigenous and historic heritage management frameworks and regulation provide evidence of the continuing process of change and refinement necessary to ensure approaches reflect community will and achieve conservation outcomes. Despite this, a growing sense of dissatisfaction with the government regarding its failure to provide strong leadership and direction for heritage management is evident.

On the one hand, there is concern voiced by Indigenous people and others that current statutory mechanisms lack credibility and effectiveness and are not sufficient to conserve our irreplaceable cultural heritage. On the other hand, some heritage owners (public and private) contend current heritage laws impose onerous cost burdens, restrict development, and provide little certainty in the statutory approval process.

With regard to Indigenous cultural heritage protection, there appears to be discontent and a heightened consciousness about the level of destruction and the lack of systematic and robust data. This is occurring at the same time that Indigenous people are demanding genuine engagement in decision-making about the management and conservation of their heritage. Moreover, the statutory focus and "blanket protection" of Indigenous archaeology within a system that is perceived to regulate destruction rather than protect culture and heritage has been challenged. The authority and validity of the scientific paradigms applied to Indigenous archaeology have also been questioned in a context where communities are endeavoring to achieve recognition and the conservation of deeper intangible values such as knowledge, song, and dance. Some legislative reforms have provided for the integrated assessment and protection of values, including intangible values and an increased level of community involvement. Yet, overwhelming heritage regulation and protection is still biased toward physical evidence and much archaeology continues to be practiced as an objective science based on the modernist processual model, in vogue when much of Australia's heritage legislation was enacted (Colley 2002). It could be argued, however, that the failure to deliver the protection of Aboriginal heritage is not entirely the result of flawed legislation but may be more due to the lack of political will and beleaguered public administration.

Reflecting broader influences in the field, the protection of cultural landscapes and intangible values has received considerable attention, and the scope of heritage continues to broaden. The widening definition of heritage and the increasing emphasis on intangibles such as language, story, and cultural practices raises challenges for Australian governments in developing appropriate legislative and protective management systems. This trend toward inclusivity is at odds with that of government, particularly at federal level, whereby the philosophy underlying the concept of the National Estate as a representation of our "full environmental and cultural history" has been rejected in favor of a system which protects a "few national jewels" (Yencken 2008).

International Perspectives

Australia is a signatory to many international charters and conventions and continues to play a prominent role in heritage internationally through the activities of ICOMOS.

Founded in 1976, Australia ICOMOS is a national chapter of ICOMOS International. In 1977, ICOMOS members met in the historic mining township of Burra, South Australia, and focused on preparing a version of the *International Charter for the Conservation and Restoration of Monuments and Sites* (the Venice Charter) which would be suitable for conservation practice in Australia. The *Australia ICOMOS Charter for the Conservation of Places of Cultural Significance* (the Burra Charter) was adopted in 1979. The Burra Charter accepted the principles and philosophy of the Venice Charter but placed greater emphasis on the conservation of culturally significant heritage places rather than ancient monuments and buildings.

Members of Australia ICOMOS attend the triennial ICOMOS International General Assembly, and many Australian members have positions on ICOMOS International Scientific Committees including twentieth-century heritage, cultural landscape, archaeological heritage management, polar heritage, and interpretation and presentation to name a few. Presently, Australia has an elected member of the Executive Committee of ICOMOS International.

Future Directions

Australia's governance, combined with the framework of statues, land use planning and management regimes, inventories, and registers, has

resulted in cumbersome heritage management system. Generally, separate Acts still protect natural, Indigenous, and historic heritage. This frequently results in fragmented heritage assessments and inadequate protection that fails to acknowledge the complex and significant interrelationships that exist between nature, history, places, objects, values, and people.

In Indigenous heritage, trends include a greater emphasis on Indigenous engagement (especially native title owners and claimants) and a shift toward values-based assessment methodology, combined with steps toward proactive rather than a reactive system for heritage protection.

With regard to historic heritage, governments appear to be less willing to list heritage places where objections are raised. This approach follows the findings of the Productivity Commission (2006) report. Unless alternatives are explored such as tax incentives or advisory services, heritage is likely to continue to be perceived by some as an economic burden.

What has emerged as a key issue since the Council of Australian Governments clarified the role and responsibility for governments at federal, state, and local levels is just how vulnerable our heritage is particularly when government funding has declined appreciably and population growth, urban development, economic growth, and climate change continue apace (State of the Environment Committee 2011). In response to these ongoing and emerging threats, the future direction for heritage is dependent on political will and continuing community regard based on a shared understanding that heritage is our inheritance from the past and constitutes an important part of our cultural identity which is worth passing on to future generations.

In the 2011 State of the Environment Report, two key issues are identified that are determined to have the most significant impact on the integrity and future condition of Australia's heritage. Firstly, government will need to play a part in the preparation of heritage assessments that provide representative and adequate areas of protected land and comprehensive heritage listings. Secondly, and perhaps most importantly, governments, heritage places owners, and communities will have to manage places in response to the known and emerging threats and in the face of diminishing resources by adopting an approach that is based on the integration of and respect for different forms of knowledge (State of the Environment Committee 2011).

Perhaps the release of the Australian Heritage Strategy Public Consultation Paper in April 2012, with its accompanying series of essays, is evidence that the federal government may be committed to once again assuming a leadership, whether this is the case remains to be seen.

Australia: Indigenous Cultural Property Return

Cressida Fforde
National Centre for Indigenous Studies, The Australian National University, Canberra, ACT, Australia

Introduction

Although there are some earlier exceptions, the return of Aboriginal and Torres Strait Islander cultural property from museums in Australia has been a point of significant debate since the 1970s. Driven by the voice of Indigenous Australians and undertaken in often tense dialogue with museum professionals, anthropologists, and archaeologists (and these groups are not necessarily all mutually exclusive), the debate has led to significant development in museum ethics, policy, and practice in Australia, a change in the way that "ownership" of such items (and thus decision making about, or influence over, them) is viewed, and has consequently resulted in the return of some types of cultural property to Indigenous groups in this country (Turnbull and Pickering 2010; Pickering 2011). The Australian history of the return of Indigenous cultural property is an informative case study, as similar changes within the same time frame occurred in other countries with indigenous populations, such as New Zealand, the United States, and Canada, and because Aboriginal people were prominent in bringing the repatriation issue to international attention, influencing policy change and instigating debate

in a number of countries overseas (Fforde and Ormond Parker 2001; Simpson 2002).

Definition

Although there are particular legal definitions used in international conventions and national legislation, in its broadest meaning, the term "cultural property" encompasses any item which has been produced by a group or culture. The terms cultural "property," "heritage," "material," and "objects" are often interchangeable in common parlance, although the term "property" often implies concepts of ownership more than the others, and while intangible heritage is widely accepted as part of cultural "heritage," it is less frequently incorporated into definitions of cultural "property." However, definitions will vary depending upon cultural context and may differ particularly depending upon their use in legal instruments.

In the repatriation context in Australia, the particular emphasis in the return of cultural property has been upon human remains and objects of special significance (usually secret/sacred, ceremonial, and sometimes funerary objects). What is defined as "human remains" has also been a point of discussion and again can vary depending upon cultural context and museum policy. In particular, it has been debated whether remains which have been made into (or incorporated into) objects should, or should not, be considered as "the deceased" and thus be covered by relevant repatriation policy. What an institution may consider to be "human remains" may not necessarily accord with what a claimant community considers to be within this category. In addition, although the identification of the supply of copies (digital or otherwise) of images and sound recordings as "repatriation" by some institutions is arguably not strictly correct (as originals are not provided or, in cases such as sound recordings, were not removed), the program of holding establishments and community organizations to provide/acquire such items is also frequently considered to fall within the "return of cultural property" rubric and ethos and is (and has been) a significant movement in itself.

The majority of Indigenous cultural property in Australian museums has been acquired over the past 150 years. Before this time, such items were generally sent overseas. They were acquired by Australian state and regional museums and also by university departments, learned societies, and private collectors. Up until the Second World War, human remains were obtained largely for the purposes of studying racial difference and were taken from wherever the dead could be found. Collections include skeletal material in the great majority, most commonly crania, but soft tissue remains were also acquired. With the demise of race-based science in the postwar period, remains were increasingly placed in collecting institutions via archaeological excavation, with scientific interest increasingly focused on areas such as paleodemography and paleopathology. In Australia and North America, it was common for Indigenous human remains found by chance, say in the course of construction, to be placed in collecting institutions (often via the police or coroner) rather than to be reburied as European remains would have been if discovered in similar circumstances. It was an example of this type of differential treatment that led to the beginning of the reburial movement in the USA (Zimmerman 1989: 60–61).

Until at least the 1970s, the evidence that the acquisition of human remains by whatever means had been undertaken with the permission of kin or source communities (or even with their knowledge) is limited, if not completely absent. Indeed in the nineteenth century, there is enough evidence within the historical literature to show that collectors were aware that their activities were not supported by Aboriginal or Torres Strait Islander people, with clear instances of concern and opposition documented, as well as some examples of requests for return (Turnbull 1994). From the 1970s onwards, legislation has been adopted at State, Territory, and Federal level that is designed to protect Indigenous sites and significant cultural property from the type of acquisition and export practices that were so common previously. Such legislation provides legal requirements for action,

Australia: Indigenous Cultural Property Return, Table 1 Summary of Australian State, Territory, and Federal legislation providing protection for Aboriginal and Torres Strait Islander heritage, including sites, human remains, and objects. for example (which includes consultation with source communities), should human remains be discovered or objects be at threat of international export. Key pieces of Australian legislation are summarized in Table 1.

The development of policy and practice relating to the return of Aboriginal and Torres Strait Islander human remains and significant cultural material occurs to a degree in tandem, and their history is interlinked. However, there are significant differences, and for this reason, a brief, separate, history of each is provided here.

Human Remains

With the exception of some early examples of requests for the return of remains that have been documented in the nineteenth and early twentieth centuries, in Australia, the start of the campaign for the return of human remains in collecting institutions and those newly discovered through construction can be traced to the late 1960s. Aboriginal law and that of Torres Strait Islander people holds that the deceased must be interred with appropriate ceremony on their traditional country and people have a responsibility to ensure that this occurs, with the potential for serious consequences if it does not. Circumstances of the removal and scientific use of remains have also been voiced as a matter of deep concern, particularly in relation to the role that racial science has played in the colonial process (Hubert 1989). Respect for the wishes of the dead was a primary consideration voiced by those at the forefront of the campaign for the return of Aboriginal remains, such as the Foundation for Aboriginal and Islander Research Action (FAIRA) and the Tasmanian Aboriginal Centre (TAC) (e.g., Weatherall 1989; Mansell 1990; TAC 2001). Those who argued in support of the retention of remains did so on the basis of scientific importance and the loss of knowledge that would result if they were reburied (e.g., Mulvaney 1991). However, the history of the reburial movement traces an increasing shift in museum and disciplinary ethics, policy, and practice away from this stance to one that continued to recognize the scientific importance of remains but recognized also the preeminent right of Indigenous Australians to determine the future of their ancestral remains whether housed in museum collections or newly discovered (Webb 1987; Fforde and Hubert 2006; Pickering 2011).

By the early 1970s, some Australian museums were beginning to change their policies regarding the accession and curation of human remains, including resolution to no longer accept newly discovered Aboriginal remains without express permission from the source community, and to remove remains from display. This decade also witnessed the first examples of the return of remains to communities, such as that in 1976 by the Australian Institute for Aboriginal Studies (AIAS – now the Australian Institute for Aboriginal and Torres Strait Islander Studies (AIATSIS)) of skeletal remains discovered in a Melbourne

garage, to the appropriate community on Groote Eylandt. However, the most significant event to occur during this period was the return of Truganini's remains to the Tasmanian Aboriginal community in 1974 following decades of campaigning by this community and their supporters. Truganini is a famous Tasmanian Aboriginal woman in history whose stated wish for her bones not to become part of a museum collection was recorded by the Reverend H.D. Atkinson in 1869. Despite this, her remains were dug up shortly after her funeral and were later placed on display in the Tasmanian Museum (now the Tasmanian Museum and Art Gallery). A history of the eventually successful attempts to have Truganini's remains returned to the Tasmanian Aboriginal community and her wishes respected can be found in Ryan (1981).

In the 1980s, Aboriginal campaigns for the return of remains from institutions in Australia achieved notable successes, including government support and the amendment of legislation that might restrict museums from deaccessioning such items. During this decade, groups received remains from, for example, the Tasmanian Museum and Art Gallery and the Queen Victoria Museum in 1984, from the National Museum of Australia in 1986, from the University of Queensland in 1988, and from the Museum of Victoria in 1989. Nearly all of these returns had only been achieved after lengthy campaigning by relevant Aboriginal groups and had met significant opposition from the scientific and museum community. However, by the late 1980s, most Australian museums had adopted policies which responded positively to Aboriginal requests for the return of the remains of named or known individuals, those who had died post-contact, those whose line of descent to a modern community could be demonstrated, or those which had been obtained in "unethical" circumstances (Fforde 2004: 112). By the end of the 1990s, these categories were no longer viable, and with the successful campaign for the return of fossil remains excavated at Kow Swamp in 1991 and the unconditional return of the ancient cremated remains of "Mungo Woman" to the people of the Willandra Lakes region in 1992, broader policies encompassing all human remains regardless of age, provenance, or circumstances of acquisition became the norm.

Museums Australia is the national organization for museums in this country, and its document *Continuous Culture, Ongoing Responsibilities: Principles and Guidelines for Australian Museums Working with Aboriginal and Torres Strait Islander Cultural Heritage* (2005) well articulates the new approach to Indigenous collections. And while Australia has no legislation regarding the return of human remains to compare with that of the *Native American Graves and Repatriation Act* (1990) in the USA, through State legislation and museum policy (both individual and via representative bodies), it is now the case that Aboriginal and Torres Strait Islander people may successfully claim the human remains of their ancestors housed in Australian museums and collecting institutions.

Significant Cultural Material

In the repatriation context in Australia, significant cultural material is generally considered to be those items classified as secret/sacred objects, a large number of which were acquired by museums and private collectors. As defined by Museums Australia (2005: 19), "Secret/sacred materials are items of special religious and spiritual significance to Aboriginal and Torres Strait Islander peoples. They have an associated tradition of restricted access and have never been accessible to all members of a community. Such items are usually associated with men's and women's private ceremonies which are not open to outsiders or to certain people within their society of origin." Cultural context is important in the definition of objects as secret/sacred and their degree of restriction; thus Museums Australia recognizes and acknowledges that it is "the community of origin who ascribe the special status of cultural material and knowledge" (2005: 19).

Responding to Aboriginal concerns, in the early 1970s, some Australian museums began to remove secret/sacred objects from display and to place them in storage areas inaccessible to the public. This decade also witnessed the first return of such items to keeping places established in

some remote communities. The South Australian Museum (SAM) in Adelaide, which had acquired significant numbers of secret/sacred objects particularly from Central Australia, played a prominent early role in developing dialogue with communities about the future of these items in its collections. When reflecting on this history, the Senior Curator and Director later noted, "Since their removal from the public gaze, sacred objects have become a difficult issue for museum curators. If such objects cannot be displayed, then it was clear that as objects of research and publication they were not an easy category with which to deal" (Clarke and Anderson 1997: 172). Indeed, removal from display and placement in museum storage did little, if anything, to increase the chances of access to these objects by their traditional owners or even to increase the chances of their knowing what was held in collections.

Serious discussions at the SAM were prompted in the early 1980s by a fortuitous visit from a group of senior Aboriginal men who were in Adelaide to try to stop the sale of secret/sacred objects collected by Professor T.G.H. Strehlow which were then in private hands (Clarke and Anderson 1997: 173). They were shocked to discover large collections at the SAM of which they had no prior knowledge, and the Museum in response undertook to "get its house in order" (Clarke and Anderson 1997: 173). Increasing realization of the extent of museum holdings then led to requests being sent to all museums in Australia requesting the return of secret/sacred objects. From the mid-1980s onwards, the SAM conducted extensive consultation with senior Aboriginal custodians in Central Australia to discuss the future of the secret/sacred objects in its collections, which resulted in the return of some objects and the decision by many communities to leave some or all of their objects in the museum for safekeeping, as well as visits by appropriate community members to the museum's newly built restricted access store.

In the same decade, other museums across Australia began to research their collections of secret/sacred objects and to open dialogue with traditional custodians about their future. While the SAM Board would only consider the return of secret/sacred objects, and particularly those which were still required for ceremonial function, other museums broadened their definition of what type of object was considered "returnable." Other avenues were also pursued, including the long-term loan of secular objects, commonly to community-led cultural centers. Repatriation policies such as those followed by the SAM, combined with the prevalence in collections of secret/sacred objects originating from remote areas, meant that unlike human remains, the return of secret/sacred objects has generally been more geographically confined to Central and Northern Australia.

Research undertaken by museums, Aboriginal groups, and their representatives to locate restricted material in institutional and private collections increased the amount of information available. The work of Museums Australia and its precursor, the Australian Council of Museums, to develop ethical guidelines for the management (including return) of significant cultural material demonstrates the change in the museum profession that has occurred in response to long-running Aboriginal concerns and campaigns. Thus, *Continuing Cultures, Ongoing Responsibilities: Principles and Guidelines for Australian Museums Working with Aboriginal and Torres Strait Islander Cultural Heritage* adopted by Museums Australia in 2005 clearly sets out instructions for the acquisition, return/repatriation, custodianship and access, and display of secret/sacred material, which at all times recognizes the high significance of these items and the right of appropriate Aboriginal and Torres Strait Islander people in source communities to determine their future and management.

Key Issues and Future Directions

In the case of both human remains and secret/sacred objects, it is common for these items to have been separated from any associated provenance information (if this existed). This factor, combined with their frequent placement, a consequent (often unorganized), in storage, and loss of institutional memory, has meant that considerable

research is often required to determine as far as possible how and where they were acquired. This type of information is crucial for repatriation, not only to identify the appropriate source community with whom to consult but also because communities do not wish to receive objects or the deceased who are not from their traditional country. The question of what to do with unprovenanced human remains and secret/sacred objects is a significant issue.

Some communities have established keeping places to hold secret/sacred objects – whether returned to them from museums or placed there by their custodians as other locations have become unsafe or inappropriate. As noted by Wallace and Akerman (2008), where and how best to store secret/sacred objects raises a number of questions for communities which require a variety of different solutions. A range of different types of keeping places have been established since the 1960s, and communities face practical and financial challenges in maintaining structures against often harsh climatic conditions, and sometimes vandalism and theft. Human remains are rarely planned to be held permanently in keeping places, although this may occur for a period prior to re-interment.

Funding has been a significant issue in the return of Indigenous cultural property in Australia, which can often be a lengthy and costly process for both museums and communities. Funded by Commonwealth, State, and Territory governments, the *Return of Cultural Property* (RCP) program (1993–1997) followed by the *Return of Indigenous Cultural Property* (RICP) program (1999–present) has provided funds to both museums and communities towards four specific objectives: "identify the origins of all ancestral remains and secret/sacred objects held in the museums where possible; notify all communities who have ancestral remains and secret/sacred objects held in the museums; appropriately store ancestral remains and secret/sacred objects held in the museums at the request of the relevant community; arrange for repatriation where and when it is requested" (Truscott 2006: 2). The National Principles developed by the RICP program strongly align with those of Museums Australia (2005). Nonetheless, the substantial and long-term costs for community organizations, which are associated, for example, with employment of repatriation officers, information management, community consultation, museum visits, acquiring and maintaining keeping places, and conducting funerals, are considerable and remain perhaps the most significant practical issue for communities in the repatriation process. The sheer scale of the number of human remains and secret/sacred objects acquired by collectors in Australia and overseas in the nineteenth and early twentieth centuries means that this issue will be faced by Aboriginal and Torres Strait Islander communities for many years to come.

Australia: Maritime Archaeology

Mark Staniforth
School of Geography and Environmental Science, Monash University, Clayton, Melbourne, VIC, Australia

Introduction

Indigenous sites underwater, historic shipwrecks, abandoned vessels, survivor camps, jetties, and aircraft underwater, together with the archaeological evidence associated with maritime industries such as whaling or shipbuilding, comprise the maritime archaeological heritage of Australia and its surrounding waters (Gibbs 2006; Nutley 2006). Indigenous people have been present in Australia for at least 50,000 years, and they arrived by voyaging in some form of watercraft making them among the earliest "maritime" people that we know of. While it is considered unlikely that we will ever find physical or archaeological evidence of early Indigenous watercraft, interesting experimental maritime archaeology can still be attempted. Furthermore, as a result of rising sea levels since the Last Glacial Maximum (LGM), some of the earliest terrestrial archaeological sites associated with Australia's Indigenous peoples have been inundated and now lie beneath the sea (Nutley 2006: 84–88). As a result part of the maritime archaeological record in Australian waters potentially goes back at least 50,000 years.

We know that the Dutch, both deliberately and accidentally, came into contact with Australia after 1600 CE. Soon afterwards Dutch, British, and other vessels began to be wrecked around Australia with the first, that we know of, being the English East India Company ship *Trial* lost in

1622 (Green 1977). Over the next 400 years, thousands of vessels were lost in the waters around Australia, and since the early 1970s, maritime archaeologists have conducted a number of significant excavations of historic shipwrecks in Australia (Nash 2006: 55–68). In addition, while there has been a focus in Australian maritime archaeology on "historic shipwrecks," there has also been important research on abandoned vessels, jetties, aircraft underwater, and other kinds of maritime archaeological sites (Gibbs 2006; Nutley 2006).

Definition

Maritime archaeology in Australia has included the archaeological investigation of the remains of ships (shipwrecks), boats (boat finds), other watercraft or vessels, and aircraft underwater as well as cultural material that was accidentally dropped, lost overboard, or deliberately deposited into the water body. Maritime archaeological evidence can include the remains of structures that were originally built wholly or partly underwater (such as fish traps, bridges, piers, jetties, and wharves). In addition archaeology may examine the remains of human activity that originally took place on dry or marshy land that have subsequently been inundated (or submerged), either by rising water levels or by marine (or fluvial) erosion. Maritime archaeology is a subdiscipline of archaeology associated with the sea, seafaring, and human interactions with the sea. Maritime archaeology can also include sites and artifacts that are not underwater but that are related to maritime activities such as lighthouses, harbor constructions, or shore-based maritime industries such as shipbuilding, whaling, or sealing.

Historical Background

It was the finding of two seventeenth-century Dutch East India Company (VOC) ships during the early 1960s (*Batavia* lost in 1629 and *Vergulde Draeck* sunk in 1656) that first prompted the Western Australian Government to enact legislation designed to protect shipwrecks through the *Museum Act Amendment Act* of 1964 (Jeffery 2006: 124). While this provided a legislative basis for the protection of historic shipwrecks, such as the VOC shipwrecks, there were still no trained, experienced, or qualified maritime archaeologists working in Australia in the late 1960s. This changed in 1971 when the Western Australian Museum employed Jeremy Green who had worked on shipwrecks in the UK with Colin Martin and in the Mediterranean with people like George F. Bass and Michael Katsev (McCarthy 2006: 2). Green brought others to Western Australia from overseas including Myra Stanbury and Patrick Baker who would go on to become long-serving staff members of the Maritime Archaeology Department. Also in the 1970s, other key staff including Graeme Henderson and Michael McCarthy joined the Department, and at the same time, the Materials Conservation Department was gearing up to conserve the artifacts generated by large-scale underwater archaeological excavations.

Starting in the 1970s, the WA Museum conducted a number of terrestrial and underwater excavations of VOC shipwrecks such as *Batavia* (1629), *Vergulde Draeck* (1656), and *Zeewijk* (1727) as part of what was known as the Dutch Shipwrecks Program (Green 1989). Excavations of later period sites like the ex-slaver *James Matthews* (1841), the merchant vessel *Eglinton* (1852), and SS *Xantho* were conducted under the Colonial Shipwrecks Program (McCarthy 2000; Stanbury 2003; Henderson 2009). The excavated assemblages are held by the Maritime Archaeology Department and some material is now on display in the Western Australian Maritime Museum Shipwreck Galleries in Fremantle (Hosty 2006: 155–57; Fig. 1).

In 1976 the Australian Federal Government (the Commonwealth of Australia) enacted the *Historic Shipwrecks Act* (*HSA*) 1976 which fundamentally changed the basis for legislative protection and management of historic shipwrecks in Australia. By 1988 all states and territories had enacted state legislation for the protection of historic shipwrecks and/or requested that the Federal government apply the *HSA* to waters off their

Australia: Maritime Archaeology, Fig. 1 Excavation of a mass grave from *Batavia* shipwreck on Beacon Island (Western Australian Museum)

coastlines. As a result of amendments to the legislation in the early 1990s, the *Historic Shipwrecks Act* 1976 now provides legislative protection to all shipwrecks (but not other kinds of underwater cultural heritage such as aircraft) which sank more than 75 years ago (a rolling date) and that are located in the territorial seas, contiguous zone, and Exclusive Economic Zone (EEZ) from the High Water Mark out to 200 nautical miles offshore (Jeffery 2006: 123–36).

Key Issues

Education is identified as the first key issue as maritime archaeology is a multifaceted discipline that requires both theoretical learning and practical skills training. Fortunately Australia has been one of the few countries in the world that has a long and sustained tradition over more than 30 years of running tertiary education courses in maritime archaeology. The need for tertiary level teaching in maritime archaeology in Australia was first acknowledged in the mid-1970s when the Western Australian Museum canvassed several options for university teaching in maritime archaeology including a 3-year Bachelor's degree course and a Graduate Diploma. In 1980, a 12-month Graduate Diploma in Maritime Archaeology (GDMA) was introduced by the WA Institute of Technology (later renamed Curtin University) and was taught in association with the Department of Maritime Archaeology at the WA Maritime Museum. The GDMA was offered on five occasions between 1980 and 1995 (in 1980/81, 1981/82, 1986, 1990, & 1995/96). At different times since 1990, universities in Western Australia (Curtin University and the University of Western Australia), Queensland (James Cook University), and South Australia (Flinders University) have all offered undergraduate and/or postgraduate courses as well as research higher degree (Ph.D.) supervision (Staniforth 2009). Currently Flinders University has the largest and most active teaching and research programs at an Australian university (Fig. 2).

The second key issue revolves around the activities of the Australasian (formerly Australian) Institute for Maritime Archaeology (AIMA) and volunteer involvement in Australian maritime archaeology. One of the great strengths of Australian maritime archaeology over the years has been the activities of AIMA, which was formed in Adelaide in 1981.

Australia: Maritime Archaeology, Fig. 2 Flinders University Intensive Program in Underwater Cultural Heritage, 2009 (Maritime Archaeology Program, Flinders University)

Membership of AIMA includes not only trained, professional maritime archaeologists (which would be a very small and exclusive club indeed) but many other interested people including volunteers. One important contribution made by AIMA has been the regular publication of *The Bulletin of the Australian Institute for Maritime Archaeology* initially twice a year but in recent years only once a year as well as a quarterly newsletter that is available on the AIMA website. Another has been the regular annual conferences that have been run by AIMA for nearly 30 years, usually in September which not only bring together most Australian maritime archaeologists and underwater cultural heritage managers each year to talk about their work, exchange ideas, and hold various meetings but have also provided the opportunity for many others to come to Australia from all over the world. For a decade now the annual AIMA conference has usually been held jointly with the annual conference of one or more of the other related organizations in Australia (and New Zealand) including the Australasian Society for Historical Archaeology (ASHA), the Australian Association for Maritime History (AAMH), and the Australian Archaeological Association (AAA). In the late 1990s AIMA purchased a license to run the internationally recognized Nautical Archaeology Society (NAS) training program, which was then tailored to suit the Australian situation as the AIMA/NAS training program which has proved of enormous benefit by providing a flow of new membership, fulfilling important public education and awareness needs, as well as being used by universities for training students. AIMA also provides a national umbrella body for the avocational (amateur) organizations that exist in some, but not all, Australian states including the Maritime Archaeology Association of Western Australia (MAAWA), the Society for Underwater Historical Research (SUHR), and the Maritime Archaeology Association of Victoria (MAAV).

Research is the final key issue but has always had a relatively strong track record in Australian maritime archaeology, which has contributed to the development of the methods used in maritime archaeology worldwide (Green 1990) as well as to our understandings of specific aspects of shipbuilding and large-scale historical processes including colonialism, consumerism, and capitalism (Staniforth 2003). This chapter will examine three case studies of historic shipwreck excavations of vessels that date from the last decade of the eighteenth century: HMS *Sirius*, HMS *Pandora*, and *Sydney Cove* in order to consider some of the key issues in maritime archaeology in Australia that have arisen over the last three decades.

HMS Sirius (1790)

HMS *Sirius* was the flagship, and largest, Royal Navy vessel to accompany the First Fleet to Australia in 1788. In 1790 under the command of Captain John Hunter, and together with HMS *Supply*, the vessel made a voyage to Norfolk Island to transport convicts and Royal Marines to that island in order to establish a colony there. For HMS *Sirius*, the voyage ended in disaster on 13 March 1790 when the ship was driven backwards onto the reef near the new settlement of Kingston (Nash 2006: 56–58; Stanbury 2007: 25–26). The wreck of HMS *Sirius* was a highly significant event in Australian history generally and specifically in the history of Norfolk Island. The connections to the events of the First Fleet and British convict settlement of Australia make the site of great significance to Australians.

Three seasons of fieldwork were conducted in 1985, 1987, and 1988, with funding from the Australian Bicentennial Authority (ABA), sponsorship from private companies, and support from a number of museums and government agencies. These archaeological expeditions were led by maritime archaeologist Graeme Henderson from the WA Museum and included a team of about 12 experienced professional maritime archaeologists and avocational volunteers (Henderson and Stanbury 1988, Stanbury 2007). A fourth expedition funded by the Australian Federal Government's Historic Shipwrecks Program took place in 2002 (Fig. 3).

The site is located in very shallow water of two to three meters depth that is regularly subjected to very heavy wave action. Experience gained on shallow water "surf-zone" sites in Western Australia, such as *Batavia*, had demonstrated that valuable information could still be obtained from such sites. The survey and recording work was carried out using SCUBA equipment and conducted from an inflatable dive boat anchored on the seaward side of the surf zone. Apart from a substantial ballast pile consisting of cast-iron ballast pigs (or ingots) known as "kentledge," most of the artifacts were located in gullies and holes in the limestone reef flat. The four expeditions, and a program of artifact conservation and cataloguing carried out over the last 20 years and largely funded with grants from the Federal Government's Historic Shipwrecks Program, have provided accurate survey data as well as raising and conserving hundreds of small artifacts. The archaeological assemblage contained a wide variety of material from a copper coin to large anchors, but most consists of material primarily associated with the structure of the ship, its

Australia: Maritime Archaeology, Fig. 3 View from seaward with dive boat and surf breaking over *Sirius* wreck site (Western Australian Museum)

fastenings and fittings, and a smaller amount of equipment and personal belongings relating to the crew and passengers.

A number of specialist reports have been written and articles published in respected international journals such as the *International Journal of Nautical Archaeology* (IJNA) as well as a popular paperback book called *Sirius – Past and Present* (Henderson and Stanbury 1988; Stanbury 2007). Artifacts from *Sirius* are now on display both in the lower floor of the Norfolk Island Museum (Pier Store) on Norfolk Island and some loan material has been on display at the Australian National Maritime Museum (ANMM) in Sydney. In addition some material from HMS *Sirius* was incorporated into a major exhibition that toured Australia during 1988 and 1989 titled *Shipwreck – Discoveries from our Earliest Shipwrecks 1622–1797*. (Hosty 2006: 160–61).

HMS Pandora (1791)

As a consequence of the famous and well-documented mutiny on HMS *Bounty* on 26 April 1789, the Royal Navy dispatched the 24-gun frigate HMS *Pandora* under the command of Captain Edward Edwards to the South Pacific in 1790. After capturing some of the mutineers, HMS *Pandora* ran onto a reef-top during the night of 29 August 1791 and the next day sank into deeper water (Gesner 1991, 2007; Nash 2006: 58–62).

In November 1977 the site of HMS *Pandora* was relocated by two rival groups of divers with the assistance of an airborne magnetometer carried aboard an RAAF (Royal Australian Air Force) maritime reconnaissance aircraft. The wreck was reported to the Australian Federal Government and initially inspected in April 1979 by a team led by maritime archaeologist Graeme Henderson, and including Patrick Baker, from the WA Museum. The site is in an extremely remote location, some 50 nautical miles offshore, which would normally fall outside the claimed offshore jurisdiction of many countries, certainly during the 1970s. Nevertheless, Australia had recently passed the *Historic Shipwrecks Act* 1976 which claimed a 200 nautical mile jurisdiction and so HMS *Pandora* was declared as a historic shipwreck in November 1979. The Queensland Museum was made responsible for managing historic shipwrecks in Queensland including HMS *Pandora* and in 1981 the Museum appointed Ron Coleman as curator of maritime archaeology. Also in 1981 HMS *Pandora* was given protected zone status that requires a permit to enter a zone extending for a radius of 500 m from the wreck. The site is still a protected zone, which probably makes it one of the longest periods (now 27 years) of direct, and effective, government control over access to a historic shipwreck anywhere in the world.

Between 1983 and 1989 the Queensland Museum undertook several expeditions to survey and partially excavate the site. Initial funding came from the Australian Federal Government, and with support from maritime archaeologists in a variety of interstate organizations, as well as volunteers, some test excavations were completed and a permanent grid structure was established on site. It was found that a substantial section of the ship's lower timbers had survived on the starboard side including relatively intact areas of the lower hull as well as the collapsed remains of upper works and cabins with their contents (Gesner 1991, 2007).

The remains of HMS *Pandora* lie in approximately 30–34 m of water which, together with the remote location more than 600 km from the nearest major port (Cairns), makes any archaeological investigation both person-intensive and expensive. By about 1990 the problems of the short dive times allowable with SCUBA diving and having to hire "live-aboard" vessels for large teams had led to the conclusion that without large-scale funding, the excavations should probably cease. Expeditions in 1993 and 1995 concentrated on sediment and core sampling with only limited excavation but, importantly in light of subsequent developments, trialled the use of Surface-Supplied Breathing Apparatus (SSBA) that increased dive times and improved communications (Gesner 2007; Fig. 4).

The situation changed in the mid-1990s when the Queensland state government offered the Queensland Museum $1,000,000 for the project, subject to matching funds being raised from the private sector. The nonprofit *Pandora* Foundation

Australia: Maritime Archaeology, Fig. 4 Diver next to one of *Pandora*'s main anchors (Western Australian Museum)

was established in Townsville in 1996 and raised a further $2,500,000 from local businesses and donations, which placed the *Pandora* project back on track to continue excavations. The Queensland government subsequently also announced that it would provide more than $17,500,000 for a major museum development (the Museum of Tropical Queensland) in Townsville which would house and exhibit the *Pandora* material in one of the new museum's major galleries (Hosty 2006: 158).

A series of five expeditions between 1995 and 1999 raised several thousand artifacts including ship's equipment, human skeletal remains, crew items, and "collected" artifacts from the Pacific islands (Gesner 2000, 2007). Over the years a number of research reports, catalogues, and commentaries based on the material culture assemblages from HMS *Pandora* have been completed (Gesner 1991, 2007). The "collected" artifacts or "artificial curiosities" are of considerable interest for what they tell us about the cultural interactions between the "West" and the "Other." British exploration vessels and their crews would collect the material culture of the Indigenous inhabitants of Australasia and the Pacific. The collected artifacts from HMS *Pandora* are of particular importance as they represent collecting by all social strata among the *Pandora* officers and crew, rather than just the "official" or elite collections that made their way into collections of the British Museum, Museum of Natural History, and the like. After the 1999 expedition the project focussed on the opening of the new Museum of Tropical Queensland in April 2000 and, despite plans to continue excavation work, no further expeditions have taken place to date (Nash 2006: 62). There is considerable maritime archaeological potential remaining on the HMS *Pandora* site, particularly in the bow area, which has not been excavated to date. In addition, the existing archaeological assemblages provide excellent comparative collections for other investigations of late eighteenth-century Royal Navy vessels in other parts of the world.

Sydney Cove (1797)

Sydney Cove was wrecked on 9 February 1797 during a voyage from Calcutta in India to the newly established, penal colony at Port Jackson (Sydney). The merchant vessel had been consigned by Campbell and Clark, a small trading enterprise involved in trading European, Indian, and Chinese goods, primarily around the coasts of the Indian subcontinent, and for whom trading to Australia would be a new venture (Staniforth 2003: 65–99; Nash 2009). It was carrying a speculative, mixed cargo including bags of rice, sugar, tobacco, salted meats, tar, vinegar, soap, candles, leatherware, Indian textiles, livestock, Chinese

porcelain, as well as 7,000 gal (31,500 l) of rum (Nash 2009: 32–53).

The site of *Sydney Cove* was relocated by sports divers in January 1977 in only 4–6 m of water, approximately 400 m off Preservation Island in Bass Strait. Despite the recent enactment of the Commonwealth *Historic Shipwrecks Act* (1976), the Tasmanian government proclaimed the underwater site itself, and the associated land sites where a part of the salvaged cargo had been stored and the survivors' camp was located, as a Historic Site on 29 March 1977 under the Tasmanian *National Parks and Wildlife Act* 1970. Survey work and test excavations were undertaken in the late 1970s and further work was carried out in the 1980s to install permanent survey controls around the wreckage. Some artifacts including the partially intact rudder and two cannon were raised during this early work (Nash 2009: 94–99).

An extensive program of archaeological excavation on the underwater site was carried out between 1991 and 1994 under the direction of Mike Nash of the Tasmanian Parks and Wildlife Service, with funding from the Federal Government Historic Shipwrecks Program and conservation assistance from the Queen Victoria Museum in Launceston. Support also came in the form of personnel and equipment from federal and interstate government agencies backed up by numerous volunteers. Diving operations were conducted using surface-supplied air from an 11-m charter vessel *Strait Lady* and SCUBA tanks were only used for some photographic and video recording. A total of 216 m^2 of the site was excavated using water dredges and underwater recording was carried out with a rigid grid frame system. Among the artifact assemblages were more than 200 kg of mostly broken polychrome overglaze and blue underglaze Chinese Export Porcelain, which was commonly imported into the Australian colonies before 1830 which, in addition to its functional utility, tells us about some of the meanings attached to ceramics in the early colony (Staniforth and Nash 1998; Staniforth 2003: 86–99). The excavation also revealed interesting features about the construction of *Sydney Cove* such as the use of traditional Indian methods of protecting the hull including the use of waterproof resins and a thin layer of sacrificial planking, over which the latest imported technology of copper sheathing, over a backing of woollen felt, was laid. The final expedition in March 1994 recovered the entire site using more than 500 polypropylene sandbags, and periodic monitoring has demonstrated this to be a cheap but effective means of stabilizing the site after excavation (Nash 2009: 111, 131–4; Fig. 5).

To commemorate the bicentenary of the loss of *Sydney Cove*, an exhibition was developed which opened at the Queen Victoria Museum in

Australia: Maritime Archaeology, Fig. 5 Divers recording an excavated section of *Sydney Cove's* hull (Parks and Wildlife Service, Tasmania)

Launceston in February 1997. This exhibition travelled around Australia for 2 years funded by the Federal Government's *Visions* exhibition touring program before returning to Launceston where the archaeological assemblage is now held. In 2002 and 2004 two further terrestrial expeditions were conducted to locate and excavate part of the survivor camp, which included at least one dwelling, at the south end of Preservation Island (Nash 2009: 190–209).

International Perspectives

Australian maritime archaeology is widely respected internationally and Australian maritime archaeologists often individually, but sometimes with institutional support and backing, have taken leading roles in a variety of regional Asia-Pacific and international activities. For more than three decades, Jeremy Green of the WA Maritime Museum, for example, has taken a leading role in research and teaching maritime archaeology in Thailand, China, and Sri Lanka through programs like SPAFA as well as conducting research on Dutch East India Company (VOC) ships in Malaysia and Asian-built vessels throughout the Asia-Pacific region. Furthermore, AIMA, and individual maritime archaeologists such as Jeremy Green, support for maritime archaeology projects and programs in the Asia-Pacific region has been an important contribution to the development of the subdiscipline in the region.

Graeme Henderson, also from Western Australia, was the first head of ICUCH – International Committee on the Underwater Cultural Heritage – and he took a leading role in the drafting of both the ICOMOS Charter on the Protection of Underwater Cultural Heritage 1996 and the UNESCO Convention on the Protection of the Underwater Cultural Heritage 2001. David Nutley has been the Secretary and is now Vice-President of ICUCH and Mark Staniforth is currently a member of ICUCH. Staniforth also served for two terms on the ACUA – Advisory Council on Underwater Archaeology (2000–2008) including 3 years as deputy Chair (2001–2003) and 3 years as Chair (2004–2007) as well as 3 years on the board of the Society for Historical Archaeology (SHA) in his capacity as ACUA Chair. Wendy Van Duivenvoorde currently serves on the ACUA Board.

Future Directions

Clearly one part of the future directions for maritime archaeology in Australia lies with the tertiary education system, which has expanded in recent years partly as a result of the establishment of the Maritime Archaeology Program (MAP) at Flinders University (Staniforth 2009). Flinders University is currently the only university in Australia to develop and sustainably undertake a fully integrated program of teaching in maritime archaeology from undergraduate to research higher degree level in the form of the Maritime Archaeology Program in the Department of Archaeology. In addition to the ongoing teaching of maritime archaeology at Flinders University, it is considered likely that other Australian universities are likely to take up the teaching of maritime and underwater archaeology at various levels during the next decade. Collaborative research projects involving universities can also be expected to undergo expansion with some signs that this is starting to happen with the Australian Historic Shipwreck Protection Project (AHSPP) receiving a large ARC Linkage grant in 2011 as well as the appointment of the first post-doctoral fellow in maritime archaeology in Australia (Jun Kimura) at Murdoch University in 2012.

Australian maritime archaeology has a long history of "holistic" approaches to the integration of related underwater and terrestrial archaeological sites going back to the 1970s *Zeewijk* excavations, but recent decades have also seen the broadening of maritime archaeology activity to include the study of Indigenous sites underwater, abandoned vessels, jetties, aircraft underwater, survivor camps, and shipyards (Gibbs 2006; Nutley 2006). This kind of holistic approach is another likely future direction for Australian maritime archaeology and, together with the (eventual) ratification of the UNESCO

Convention for the Protection of the Underwater Cultural Heritage (2001) by the Australian government, is likely to provide the basis for increased activity in these areas of maritime archaeology.

On the other hand state and Federal Government funding cuts, the lack of updated legislation and the loss of positions within government heritage agencies and museums have been ongoing problems for more than a decade (Staniforth 2000) and show signs of continuing well into the future. Unfortunately the comment made in 2000 that "the legislation is seriously dated and in need of a complete rewrite" remains as true today as it was more than a decade ago (Staniforth 2000: 91). The same paper also suggested that "not-for-profit" and community-based organizations provided opportunities for the expansion of activity in maritime archaeology (Staniforth 2000: 91–2). While the opportunities in the "not-for-profit" sector have seen limited progress over the last decade, there remains one area where future expansion is still possible.

Australia: Repatriation Acts

Cherrie De Leiuen
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

There are estimated to be thousands of Indigenous Australian human remains in the collections of Australian and international institutions and, in addition, hundreds of thousands of culturally meaningful artifacts (see Fforde 2004; Cubillo 2010). As such, repatriation is a significant issue in Australia for Indigenous communities and also for archaeologists and those working in museums and cultural heritage. Repatriation is also significant as part of a wider assertion of the rights of Indigenous Australians to control their own cultural material, archaeological sites, sacred landscapes, and heritage. Thus, the collections of Indigenous human remains and sacred objects on a deeper level both represent and continue the colonial process. Watson (2003) noted the importance of acts of repatriation when combined with an understanding of other legacies of British colonization, such as the entrenched social and economic disadvantages still suffered by Indigenous people, and how and why these remains have come to be in such collections. In recent years a philosophy of repatriation has been established in Australia and principles have been endorsed by federal, state, and territory ministers and governments, as well as museums. There is no overarching legislation equivalent to the NAGPRA in the United States, but since 2000, individual acts of repatriation have been undertaken as a matter of policy by successive federal governments. In practice this is done through the administration of the Indigenous Repatriation Unit, which negotiates with both overseas and domestic institutions, but efforts to put forward claims are primarily driven by Indigenous communities. The code of ethics of the Australian Archaeological Association (AAA), one of the largest archaeological organizations in Australia, requires that members acknowledge the importance to Indigenous peoples of ancestral remains, objects, and sites.

Definition

In Australia, repatriation has been referred to as the "repatriation debate" and the "reburial issue" (Fforde 2004; Wilson 2006). It concerns the return of human remains, grave goods, sacred objects, or objects of cultural significance to the individuals, groups, or nations that represent the original owners. Reburial refers more specifically to the reinterment of human remains that were archaeologically excavated. Repatriation is part of a general reassertion of Indigenous control over cultural heritage and of human rights. Following

Wilson (2006), repatriation can be defined as more than the return of "something" or "someone" and extends to include the return of authority, power, and control to Indigenous peoples. It thus allows for any important object to be returned and which signifies an important shift in power relations.

Historical Background

Museums in the eighteenth and nineteenth centuries were an expression of the western conviction in concepts of progress, classification, and empire. They displayed the trophies and curiosities of colonial expansion – the specimens, artifacts and human remains, and classification that contributed to the study of race. Theoretical platforms such as monogenism, polygenism, phrenology, eugenics, and social Darwinism reduced Indigenous people to museum curiosities and likened them to fossils for comparative anatomical analysis. When Australia was colonized by the British in 1788, Indigenous peoples collided with perceptions built on such racial theories. Consequently, Indigenous Australian human remains were procured to expand the discourse on Caucasian superiority. From colonization to the 1950s, Indigenous remains were removed, without permission, from burial grounds, hospitals, and morgues, and sent, sold, or traded to museums, universities, and private collections in Australia and overseas (see Fforde 2004). Remains are known to be held in more than 180 museums and in 26 countries (Simpson 2001: 239). A multitude of false premises were put forward about the nature and origins of Indigenous Australians, with one of the most prevalent and pervasive representing them as degenerate, or "primitive," as lowest on the hierarchy of human civilization (Turner Strong 1986; McGregor 1997). A discourse of extinction emerged from the 1860s of a "dying race" and ultimately led to a culture of protectionism and the enactment of legislation such as the *Half Caste Act of 1885* (Victoria) that forced the removal of mixed race children from their parents. The forced removals of Indigenous children occurred across Australia and are now known as the "stolen generations." As argued by Watson (2003: 38–9), "by reducing Aboriginal people to wretched and doomed creatures, science wiped the European slate clean of culpability for genocide, and justified invasion."

From the mid-1960s, Indigenous organizations such as the Tasmanian Aboriginal Centre (TAC) and the Foundation for Aboriginal and Islander Research Action (FAIRA) began campaigning for the return of their "Old People" and cultural property from institutions in Australia and overseas. In 1976, the Tasmanian Museum and Art Gallery was the first museum in Australia to repatriate Aboriginal remains to community. It was also at this time that there was increased interest in Australian archaeologists studying their own continent and undertaken at Australian sites. Excavations of skeletal remains such as at Kow Swamp and Lake Mungo changed the discourse of Australian archaeology and reassessed the age and nature of colonization of the continent. This work provided evidence of the antiquity of Indigenous occupation, and the nature and timing of the colonization of Australia, as well as the origins of Indigenous Australians, are still principal research areas.

In 1984 the *Aboriginal and Torres Strait Islander Heritage Protection Act* (APA) was adopted. The *APA* (*1984*) was successful in establishing dialogues between museums and Indigenous communities on the repatriation process. However, in the same year the Australian Archaeological Association (AAA) gave only conditional support to the return of human remains to Indigenous communities and to what it saw as the *destruction* of remains, (such as those discovered at Kow Swamp and at Lake Mungo), arguing that this constituted a loss of artifacts which could impact the understanding of human cultural development or biological evolution (Meehan 1984). John Mulvaney, a leading Australian archaeologist, was cynical about the fate of human remains being wholly decided by the appropriate Indigenous community, publicly stating that these remains hold "potential clues to many issues common to all races" and that study is "significant for Aboriginal self-knowledge of their origins and cultural development." (Mulvaney 1989, 1991). Repatriation in the

1980s can thus be characterized as a debate between "science" and Indigenous "politics" (later, after requests and lobbying by communities, the Kow Swamp remains were significantly repatriated in 1990, followed in 1992 by those from Lake Mungo).

The Australian government began funding the repatriation of Indigenous Australian remains from overseas in the 1990s. This funding was first provided through the Aboriginal and Torres Strait Islander Commission (ATSIC), followed by a succession of other federal government departments. As distinct from the USA, Australia has no federal repatriation legislation, only policy. The broad responsibilities for identifying and protecting Indigenous heritage including archaeological sites lie with Australia's state and territory governments. State legislation and how it is interpreted and enforced differs. In some states, such legislation is little more than tokenistic. Indigenous heritage can be protected to varying degrees and developers can apply for a permit or certificate to allow them to proceed with activities that might affect Indigenous heritage. Watson (2003) noted that under Australian common law, there is no provision for ownership of human remains. However, institutions in Australian (and primarily in the United Kingdom) have not relinquished collections of human remains but have worked around this by classifying them as objects. The only Commonwealth Act that may support a repatriation claim is the aforementioned *APA* (*1984*). It is also unlikely that Indigenous people could claim the right to human remains under Native Title legislation, as it is confined to rights and interests in lands and waters. Watson (2003: 40) observed that Native Title rights might exist over burial grounds and in appropriate cases may be available to restrain excavations, but this has not been tested to date.

In 1998 the Australian Cultural Ministers Council endorsed a strategic plan to return human remains and secret sacred objects held in the eight major Australian museums back to their communities of origin. The resulting Return of Indigenous Cultural Property Program (RICP) was administered by the then Federal Department of Environment, Water, Heritage and the Arts (DEWHA). In 2009, the Australian government formally announced support for the Declaration on the Rights of Indigenous Peoples; of relevance is Article 12 which states that:

"Indigenous peoples have the right to the repatriation of their human remains." In August 2011 the government consolidated the international and domestic repatriation programs into one program, the Indigenous Repatriation Program, to seek the unconditional return of Indigenous ancestral remains from overseas institutions and the return of secret sacred objects from Australian major museums to their communities of origin. Australian legal recognition has effectively adhered to its obligations under the *UN Declaration* and which, in a sense, allows it to be more progressive and adapted and implemented more rapidly. For example, the federal policy states that study on Indigenous human remains must be undertaken with consultation and with the informed consent of traditional owners or their identified representatives and that invasive physical research, such as the sampling of teeth, should not be undertaken.

In terms of Australian museums, repatriation is managed by eight collecting institutions: the Australian Museum, the Museum and Art Gallery of the Northern Territory, Museum Victoria, the National Museum of Australia, the Queensland Museum, the South Australian Museum, the Tasmanian Museum and Art Gallery, and the Western Australian Museum. The "Previous Possessions, New Obligations" policy (PPNO) was instigated in 1993 by Museums Australia. The PPNO was important in that it attempted to build relationships with Indigenous communities by way of Indigenous employment, by gaining their input into policy formulation and by increasing their representation on museum boards. Assistance is still provided where necessary by the National Museum of Australia and/or the relevant major state or territory museums to the federal Indigenous Repatriation Program, including research to establish the provenance of ancestral remains and the identification of overseas collections of ancestral remains and the holding of remains in temporary "keeping places."

There have been over 1000 repatriations to communities in Australia since 2000. Notable among these are the 2003 return of the remains of over 300 ancestors of the Ngarrindjeri nation

from the University of Edinburgh in collaboration with the National Museum of Australia Repatriation Unit and, in the following year, another 74 from Museum Victoria under the RICP, as well as the Oxford Museum. In 2011 the Natural History Museum in London returned 138 ancestral remains to the Torres Strait Islands in the largest single return to Australia to date. Also in 2011, an important precedent was set with the Smithsonian Institution's National Museum of Natural History's first international repatriation when it returned ancestors to the community of Gunbalanya in West Arnhem Land. This is also an example of positive collaboration – here between the community and archaeologist Sally May. In this situation, it was May's research for her dissertation and subsequent publication (May 2010) that acted as the catalyst for the repatriation process.

Key Issues, Current Debates, and Future Directions

Following the ratification of The Vermillion Accord in 1989 by the World Archaeological Congress (WAC), the Australian Archaeological Association (AAA) identified a need for a code of ethics endorsing Indigenous control of their cultural heritage. The code of ethics was adopted in 1992 and amended in 2004; it makes clear that the primacy of ownership, curation, and protection of skeletal remains must ultimately reside with Indigenous Australians. It must be noted that the majority of Australian archaeologists do work with Indigenous cultural heritage and some do carry out research on skeletal remains. This, however, must be undertaken in collaborative arrangements with the permission of traditional owners and by way of negotiation. As pointed out by Smith and Burke (2003), it is difficult to measure the impact of codes of ethics of the AAA and of the Australian Association of Consulting Archaeologists Incorporated (AACAI) in terms of implementation and behavior, apart from any explicit violations of the code. However, it can be said that the vast majority of Australian archaeologists accept, support, and expect a level of Indigenous control and approval if working on Indigenous sites (see Smith and Burke 2007). This is a distinguishing aspect of Australian archaeology.

Undoubtedly, some Australian archaeologists believe that Indigenous remains are of greater value to science than to descendant communities, particularly those working with collections of human remains in museums. This position may be more difficult to defend without strong evidence of ongoing, relevant, and ethical research outcomes (such as publications). Archaeologists do not stand alone from the moral compass of the broader community; there is a need to demonstrate responsiveness to the needs and aspirations of both Indigenous and non-Indigenous communities. Working ethically also requires a consideration of changing social attitudes (such as the reconciliation movement in Australia) and of whether it is acceptable to treat the human remains of Indigenous and non-Indigenous people differently. Simpson has argued "if museums are to demonstrate they have shaken off the colonial mantle they must address fully the issue of repatriation. To have a blanket 'no returns' policy reflects a failure to recognise or acknowledge the relevance of the concepts of spiritual ownership, cultural patrimony and the cultural importance of certain objects to cultures that did not die out in the nineteenth century, as was expected." (Simpson 2001: 246). Of course, all Indigenous cultures survive and continue today, and the repatriation process allows a handing back of some degree power and control. Positive outcomes can arise from the repatriation process and have demonstrably enabled archaeologists and museums to grow and maintain relevance, not only with Indigenous peoples but also with the broader Australian community. The point must also be made that not all Indigenous communities are antiscience nor necessarily work in opposition to non-Indigenous archaeologists (see Atalay 2008). Through the repatriation process, it may be possible to foster a greater sense of collaboration, dialogue, and capacity to gain a deeper understanding of cultural material and alternate world views.

To progress the debate, it is imperative that potential cultural material, in addition to human remains and grave goods (often termed secular objects), be repatriated. Museums frequently

display these objects, such as boomerangs, spears, shields, and clap sticks, to present a story on traditional life. These have not been included in repatriations to date, primarily as collecting institutions do not categorize them as holding the same cultural significance as human remains and known secret sacred material. This is a failure to recognize that such objects, obtained mostly without permission, may also be of significance to Indigenous peoples or that some Indigenous peoples have a spiritual connection to their cultural property regardless of its nature or age. It also fails to recognize that those outside the relevant community may not possess a complete understanding of the role and knowledge of certain artifacts nor the right to be privy to this information which should be based on social position, age, and gender.

An acute aspect of the repatriation debate in Australia concerns the support provided once human remains are returned to a community. Though Indigenous communities are in no way responsible for the removal of their ancestors and cultural material, they are required to carry the burden of the repatriation process. This involves enormous responsibility in terms of time, finances, and cultural resources, as well as an emotional burden, particularly for elders (see Wilson 2006). There is the responsibility that remains are returned in a dignified and culturally appropriate manner, with resources and land for reburial. The April 2010 Discussion Paper on the review of the International Repatriation Program by the Federal International Repatriation Advisory Committee identified a lack of appropriate land as a major problem for a number of communities, particularly if there must be a large number of reburials. This entails negotiating with federal, state/territory, local governments, and private landowners and finding relevant and appropriate sites that now, for example, are housing estates. Further to this there are also issues surrounding access and site protection. Current federal funding does not have the provisions for keeping places (either their establishment, or maintenance, or for holding remains where the specific cultural group is not able to be identified), for the purchase of land, or ongoing site management and protection. The issue of compensation has also been touched on by Hemming and Wilson (2010) and would assist with such issues. However, the issue of Native Title compensation has generated division in Australia. This raises complexities around who is entitled to compensation and on what basis, what might constitute just terms for that compensation, and who is to pay. In reality this may risk further isolating some institutions (particularly outside Australia) who are already resistant to the repatriation process.

Archaeologists have played a role in the disempowerment of Indigenous Australian communities through the appropriation and dispersal of their cultural material. Yet archaeologists do have the potential to be positive agents of change in partnership with Indigenous communities by way of acts of repatriation such as that that has occurred in Gunbalanya. Through collaboration, rigorous archaeological research can be undertaken that also has real impact, now.

Archaeological and Heritage Management Solutions Pty Ltd., Cairns, QLD, Australia

Introduction

Archaeology in Australia covers a time from around 60,000 years ago to the present day. Many of Australia's World Heritage properties consist of large protected area landscapes, and archaeological sites from all historic and prehistoric periods are likely to be contained within them. However, for the most part, the archaeological values within these landscapes have played a minor role in the presentation of the country's suite of World Heritage Areas. Exceptions to this are the Willandra, Kakadu, and Tasmanian Wilderness WHAs, which are mixed natural and cultural sites where archaeological evidence was fundamental to establishing Outstanding Universal Value (OUV). Archaeological excavation programs have also contributed to our understanding of many of the individual sites in the Australian Convict Sites WHA.

For many years following the advent of radiometric dating techniques, the quest to find the oldest site and have the final word on the first human settlement of the continent dominated archaeological debate in Australia. This quest led to many important discoveries but also limited the range of archaeological inquiry. While there is still great interest in Pleistocene sites, the post-processual movement has provided a sense of legitimacy to a range of different inquiries. New dating techniques measuring modern carbon and optically stimulated luminescence (OSL) have coincided with a rise in archaeological interest in the recent past.

The practice of so-called historical archaeology began as a way of exploring settler history. Problematically, it developed as a strand that was seen to be non-Indigenous and often involved practitioners that had no undergraduate training in Indigenous archaeology, anthropology, or history. However, a strong emergence of interest in the contact period in the 1990s led to a spate of projects that focussed on the Aboriginal settler contact and post-contact relationships.

Historical Background

Australia became a signatory to the World Heritage Convention on August 22, 1974, and has since served four terms on the World Heritage Committee. In the 38 years since becoming a signatory, 19 Australian sites have been inscribed

on the World Heritage List. Of these only three sites, the Australian Convict Sites, the Royal Exhibition Building in Melbourne, and the Sydney Opera House, have been listed for cultural values alone, and four others are mixed natural and cultural sites: Kakadu, Uluru-Kata Tjuta, Tasmanian Wilderness, and Willandra Lakes (see Table 1). To some extent, this range of sites can be understood in the context of the nation's changing understanding of "Australian" identity, advances in archaeology, and the emergence of cultural heritage as an important interdisciplinary field which has been pioneered by archaeologists.

Archaeology was not seriously practiced as a discipline until 1929 with the first systematic excavation at Devon Downs Rockshelter on the lower Murray River (see Mulvaney and Kaminga 1999). The growth of archaeology in Australia reflected a growing interest in the origin of Australia's Indigenous peoples, led largely by the South Australian Museum where Norman B. Tindale worked and the Australian Museum where F. D. McCarthy was the curator. It was not until the 1960s that archaeological positions were established at Australian universities and filled by qualified personnel. A growing interest in archaeology in the 1960s and 1970s led to discoveries that radically changed both our academic knowledge and the public's perception of Aboriginal society and its antiquity.

The discovery of Aboriginal occupation sites dating to the Pleistocene altered the perception of Aboriginal people and their culture, laying to rest the idea that the continent had only recently been settled. In the Pleistocene, sea levels were much lower and the landmass now called Australia was part of a larger area scientists refer to as Sahul. Many of the earliest sites in Australia are presumed to be now submerged below current sea levels. The antiquity and geographic distribution of Pleistocene sites in Australia are important in demonstrating how humans occupied most of the continent in the Pleistocene despite climatic extremes.

While archaeological practice in Australia has been critiqued by its Indigenous people as a fundamentally colonial exercise, by demonstrating and empirically proving the antiquity of Aboriginal occupation of Australia archaeology has also undoubtedly contributed to major political shifts in the recognition of Aboriginal rights. Archaeological discoveries dramatically revised the dates for Aboriginal colonization of the continent and provided the ammunition for Aboriginal people to engage with land managers and environmentalists, pointing out that in the millennia of Aboriginal occupation, they had shaped Australia's so-called "natural" landscapes.

Key Issues/Current Debates

Pleistocene Sites and World Heritage

Australia's earliest WH sites focussed on the country's Pleistocene archaeological heritage, reflecting the impact of these discoveries.

Willandra Lakes WHA is a semiarid landscape of dried lake beds located in far southwestern New South Wales (Fig. 1). It was inscribed on the World Heritage List in 1981 for outstanding cultural and natural universal values under criteria iii and viii. Here more than any other WHA in Australia the archaeological and geomorphological evidence played a crucial role in establishing the Outstanding Universal Value of the area (see Fig. 2).

The most well-known archaeological site in Australia is the Lake Mungo Lunette in the Willandra Lakes WHA. A hearth radiocarbon dated to 31,000 years BP is underlain by another half meter of cultural deposit, suggesting that the basal date for the cultural deposit is in fact much older about 40,000 years BP; some speculate even earlier at 60,000 years ago. Mungo provides early evidence of human ritual and all it implies about the complexity of the society and cosmological beliefs of the people who left these traces. This evidence includes a 26,000-year-old burial, which is the world oldest known cremation, and a 30,000-year-old ochre burial.

In addition to addressing the timing of colonization, this WHA illustrates one of the enduring themes of archaeological research in Australia – that of human relationships with the environment through time. Other evidence from archaeological sites within the WHA includes the remains of giant marsupials and seed-grinding stones from

Australia's Archaeological Heritage, Table 1 Table of Australian World Heritage Sites inscribed for cultural value (Criteria numbers have been converted to the current numbering convention)

Number	Site name	Inscription date	Cultural Criteria	Natural Criteria	Archaeology period	Archaeology	Area Originally listed	Currently listed (ha)	Notes
185	Willandra Lakes	1981	iii	Viii	Pleistocene (indigenous)	Crucial to both natural and cultural OUV	Difficult to ascertain easily as not specified in the nomination dossier. Dossier says the Willandra lakes Region = 6000 km2 (600,000 ha)	240,000	Area reduced (19Comm Decision 1995)
147	Kakadu National Park	1981	I,v	Vii, ix, x	Pleistocene to current day (indigenous)	Archaeology important but Rock Art the most central to the cultural OUV	6,144 km2 (614,400 ha)	1,979,766	Extension 1987, 1992
447	Uluru-Kata-Tjuta	1987 inscribed for natural values. 1994 re-inscription (as cultural landscape)	V, vi	Vii, viii	Primarily Holocene	Evidence for criterion 5	132,566 ha	132,566	Again humans and environment-intensification at 5,000BP and increase in ritual intensity.
181	Tasmanian Wilderness	1983, extension plus cultural listing in 1989 (cultural)	I ii, iv, vi	Vii, viii, ix, x	Pleistocene	Yes	769,355 ha	1,407,513	+ a buffer zone of 3747 ha
1306	Australian Convict sites	2010	Iv, vi	No	Colonial 1788–1877	Supplementary although key source of information in some of the sites	1502.51 ha	1502.51	+3883.42 buffer
166	Sydney Opera House	2007	i	No	20th Century	No	5.8 ha	5.8	+buffer 438
1131	Royal Exhibition Building & Carlton Gardens	2004	ii	No	19th Century	No	26 ha	26	+buffer 55

18,000 years BP. Recently, the area has revealed poignant evidence of Australia's earliest inhabitants in the form of footprints of ancient family groups preserved in clay.

The Tasmanian Wilderness WHA was inscribed on the World Heritage List in 1982 for its natural values and extended in 1989 for both its outstanding natural and cultural universal values. It is listed under seven of the ten criteria (criteria iii, iv, vi, vii, viii, ix, x) and is one of the largest conservation reserves in Australia. Climatic changes in the ancient past influenced landscape development. Rising sea levels formed Bass Strait and the Australian mainland became inaccessible; the resulting isolation experienced by Tasmanian Aboriginal people and the cultural effects of this isolation captured the interest of archaeologists.

Kutikina Cave is one of about 40 Pleistocene sites so far discovered in the Tasmanian Wilderness WHA. However, at the time of the original nomination in 1982, there had been no systematic survey for Aboriginal sites, and Kutikina (Fraser Cave) in the Lower Franklin River was the only specific site mentioned in the nomination dossier. It was described as:

> one of the six archaeologically richest limestone caves sites in the western Pacific. A radiocarbon date from the base of part of the cave deposit indicates human occupation in the area about 21,000 years ago. . ..further research is proposed. . .It may be claimed already that an antiquity of 21,000 years establishes southern Tasmania as the most southerly known penetration of the earth's land surface during ice age times' (Nomination Dossier 1982: 13).

These sites are of great significance and their discovery contributed greatly to the campaign to protect the area from logging and from proposed dam construction. However, the original justification for listing on cultural values was only four paragraphs, while the natural values justification was nine pages long, which provides some indication of how the archaeology,

As a cultural property the region is of outstanding universal value because:

- the remains of Homo sapiens sapiens in the Lake Mungo lunette establish that modern man had dispersed as far as southeastern Australia before 30,000 years ago
- complex ritual and symbolic systems are indicated by the 30,000 years old ochred burial and by the 26,000 year old cremati (the oldest cremation site in the world)
- these skeletal remains provide amongst the earliest evidence of Homo sapiens sapiens anywhere in the world and establish the great antiquity of Australian Aborigines
- some of the world's earliest substantial evidence for the exploitation of freshwater resources occurs here in quantity
- the evidence enables a reconstruction of the economic life of Homo sapiens sapiens, showing a remarkable adaptation to local resources and the interaction between culture and the changing natural environment
- grindstones to produce flour from wild grass seeds were used here in the late Pleistocene, at much the same time as their use in the Middle East.
- pigments were transported to these lakeshores before 32,000 BP
- the typology of early Australian stone tools was defined as a result of research in this region

An aesthetic sense, ritual, and concern for deceased kin are surely the hallmarks of mankind. The Willandra discoveries have established the great antiquity and richness of Aboriginal culture and have caused a significant reassessment of Aboriginal prehistory and its place in the history of modern man. The discoveries have linked the origins of modern society in the Old World with one across Wallace's Line in Australia.

Australia's Archaeological Heritage, Fig. 2 Extract from the nomination dossier – Willandra Lakes WHA

although significant, was something of an afterthought in the assessment process. By the time the 1989 extensions were proposed, about 37 Pleistocene archaeological sites were known. The justification for inscription under criteria ii, v, and vi is more clearly articulated on the basis of its information about past Aboriginal settlement.

Rock Art and World Heritage in Australia

"Rock art is the most widespread cultural manifestation of humankind… it is a manifestation of human conceptual thought and of the beliefs that are at the heart of traditional societies" (ICOMOS 2010: 1). Aboriginal paintings, drawings, and engravings occur in many parts of Australia. There has been a wealth of research into subjects as diverse as the

contemporary meaning to Australia's Indigenous people, what the depictions reveal about environmental change and extinct species, and development of techniques for dating and recording the art itself. Significant rock art sites occur in many of the country's protected area reserves outside of current WHAs. Some highly significant sites such as those in the Burrup Peninsula, Western Australia, and in Laura in North Queensland are still at risk from development pressures. Rock art sites also exist in WHAs listed for their natural criteria alone such as the Blue Mountains WHA. However, the only WHA to date where rock art has directly contributed to the case for establishment of the OUV of the landscape is Kakadu National Park.

Kakadu National Park was inscribed on the World Heritage List in three stages over 11 years, commencing in 1981 for both outstanding cultural and natural universal values. It was listed under criteria i, vi, vii, ix, and x. The site description notes that:

This unique archaeological and ethnological reserve has been inhabited continuously for more than 40,000 years. The cave paintings, rock carvings and archaeological sites record the skills and way of life of the region's inhabitants, from the hunter-gatherers of prehistoric times to the Aboriginal people still living there. It is a unique example of a complex of ecosystems, including tidal flats, floodplains, lowlands and plateaux, and provides a habitat for a wide range of rare or endemic plant and animal species (see http://whc.unesco.org/en/list/147).

Kakadu is a landscape of dramatic vistas, renowned for its beautiful freshwater wetlands and rock art sites. The paintings cover a long chronological span, the oldest date back nearly 20,000 years and the most recent are from contemporary times. Prior to its inscription, there had been a long push to ensure that this area was conserved and protected from mining, and in fact the gazettal of a national park over part of this area arose from recommendations made in the Ranger Uranium Inquiry. While the presence of Indigenous inhabitants was noted in the original nomination dossier, the emphasis was on the archaeological evidence of the Indigenous past, rather than the contemporary Aboriginal community. It was not until the third extension nominated in 1992 (Australian Government 1992: 87–88) that the focus of the nomination dossier changed to more comprehensively incorporate the living traditions of the Traditional Owners and cultural continuity:

The cave paintings, rock carvings and archaeological sites present a record of the skills and lifeways of the region's inhabitants, from the hunters and gatherers of prehistoric times to the Aboriginal people still living there (Australian Government 1992).

This was an important shift in thinking about heritage and not just in Australia. It was around this time in 1992 that the World Heritage Committee convened a meeting of specialists to redraft the Operational Guidelines to include the concept of associative cultural landscapes more explicitly in a way that allowed for the recognition of Indigenous cultural values.

While it is the Aboriginal rock art that was the key evidence to support the inscription of this cultural property on the World Heritage List in 1981, there are also a number of Pleistocene archaeological sites in the WHA. The original nomination dossier provides a glimpse of the contemporary debates about the dates and process of Indigenous colonization of the continent (White 1971; Jones 1973). At the time of the nomination, the emerging results from Lake Mungo were challenging some of the assumptions derived from the archaeological work in the Kakadu area in the late 1960s (e.g., White 1967).

Cultural Landscape, World Heritage, and Archaeology in Australia

The changes to the Operational Guidelines adopted in 1992 defined three categories of cultural landscapes including (1) a landscape designed and created intentionally by man, (2) an organically evolved landscape, and (3) an associative cultural landscape.

Australia has actively engaged with the development of cultural landscape concepts within the Convention and quickly moved to renominate Uluru-Kata Tjuta following the successful nomination by New Zealand of Tongariro – the first cultural landscape to be listed. Uluru-Kata Tjuta

WHA remains the only cultural landscape listed in Australia. This reserve is in the arid inland and comprises extensive sand plains, dunes, and alluvial desert, dominated by the Uluru monolith and Kata Tjuta. The focus of the park has always been on the monolith Uluru (formerly known as Ayers Rock) which has drawn curious tourists since the 1940s. This interest, while a catalyst, for conservation from tourists gave rise to the long-term struggle of Anangu to retain their traditional way of life and control of their spiritual sites (Layton 1986). This WHA was first inscribed in 1987 for its natural values and it was not until 1994 that it was reinscribed for its cultural values under categories v and vi. The ICOMOS evaluation (p. 100) notes:

> To write that the landscape is *associated with* the narratives, songs, and art of the *tjukurpa*, while accurate from a western perspective, does not do full justice to Anangu ontology and is a poor translation of Anangu concepts. For the Anangu this landscape is the product of heroic ancestors' actions and can be read as a text specifying the relationship between the land and its indigenous inhabitants laid down by the *tjukurpa*. The very rock of Uluru and Kata Tjuta is proof of the heroes' actions and being [criterion vi].

Archaeological evidence of Aboriginal adaptation and change includes the introduction of new tool types and the creation of new forms of rock art as well as changes to camping patterns and social organization over the past 5,000 years. However, the recommendation of ICOMOS (1994) supporting the re-inscription illustrates that though this evidence may have been useful to authenticate the time depth and adaptive nature of Anangu society, it is their relationship and interaction with their landscape and the way it embodies their spiritual beliefs that is the core of the Outstanding Universal Value.

The Archaeology of the Recent Past and World Heritage in Australia

The Australian Convict Sites WHA (Fig. 3) is one of the nation's most recent additions to the WH List. It comprises 11 properties spread across Tasmania, Norfolk Island, NSW, and Western Australia. It was inscribed in 2010 under criteria iv and vi. It incorporates Australia's first ever WH site in private ownership. Each of these places include substantial archaeological values and several, e.g., the Female Factory, Port Arthur, the Hyde Park Barracks, and Parramatta Park, have had extensive archaeological programs associated with them; however, there is little overt acknowledgment of the archaeological values of these places in the nomination dossier.

Australia's Archaeological Heritage, Fig. 3 Student volunteers excavate the site of convict sawpits and tan pits at Port Arthur Historic Site, part of the Australian Convict Sites WHA (Image courtesy of Port Arthur Historic Site Management Authority)

In the case of the remaining cultural sites, i.e., the Royal Exhibition Building and Carlton Gardens in Melbourne (inscribed 2004) and the Sydney Opera House (inscribed 2007), a consideration of archaeological evidence played no role in their nomination. Interestingly, the Draft Conservation Plan for the Royal Exhibition Building included with the nomination dossier did not address the issue of any associated archaeological deposits and how they would be managed. This

reflects a problem with architecturally focussed heritage planning, in that it does not always include multidisciplinary input from archaeologists.

As we have seen, Australia's first cultural nominations can be understood in a national context of the dramatic discoveries of Australia's Indigenous Pleistocene past in the late 1960s and 1970s. Aboriginal activism was re-energized through the scientific discoveries of the antiquity of Aboriginal settlement, the heated environmental battles over the so-called wilderness, and large-scale development proposed in "natural" areas (e.g., Ranger Uranium Mine Inquiry, the proposed Jabiluka mine near Kakadu, and the Tasmanian hydroelectric scheme dam proposal) in the 1970s and 1980s, and the expansion of Australia's protected area reserves. Since that time, government resourcing for the assessment of new areas has dwindled, as too has resourcing for the heritage sector generally.

Heritage bodies have repeatedly lobbied the Australian government to populate its Tentative List through strategic and thematic studies to no avail. There are substantial community-driven campaigns not yet supported by government advocating consideration of a number of cultural properties including the Goldfields, Canberra, Adelaide Park Lands, Cornish mining sites Budj Bim, and the rock art of the Dampier Archipelago. Currently, the assessment of Cape York Peninsula provides opportunities for Indigenous landowners in the region to contribute to any future nomination and develop new models for cultural landscapes shaped by continuing traditions. Ongoing concern over the issues such as costs of managing World Heritage Sites, the globalization of "culture" through international processes such as the World Heritage Convention, the commercialization of significant cultural places through the conflation of world heritage as tourism, and the rights and interests of local communities is debated as hotly within Australia as elsewhere. There are conflicting political positions adopted within Australian society on the impacts of World Heritage listing on Indigenous rights which continue to hamper the development of new models driven by Indigenous Traditional Owners.

Archaeological research is nationally under-resourced compared with other areas of research. While a number of persistent archaeologists continue to carry out field research, the main forms of archaeology now practiced in Australia are consulting and salvage archaeology which are not likely to give rise to dramatic archaeological evidence, and if they do, it is often too late to save it.

International Perspectives

The human species did not evolve on the Australian continent but arrived here somehow from elsewhere. Evidence to date suggests that these first colonists were modern humans (*Homo sapien sapiens*). Just how, when, and why they arrived is still under debate. International discoveries, such as *Homo floresiensis* in 2003 not far away on the Indonesian island of Flores (Morwood et al. 2004) and a geochronologically dated site in Malaysia at 1.8 million years ago (Majid 2003), are still being made that may potentially change theories about colonization of the region. Such discoveries in turn spark new research questions for Australian archaeologists and may have implications for future transnational serial nominations.

More broadly, the relationship between humans and their environment and responses to environmental change are enduring themes in archaeological research in Australia. The specter of Global Climate Change that now confronts the world has re-energized this area of study with many researchers looking to the consequences of past change and human responses.

Australia's contribution to the articulation of the cultural landscape concept along with the listing of Uluru-Kata Tjuta WHA as a cultural landscape so quickly after the 1994 changes to the Operational Guidelines is significant within the history of the convention (Rossler 2006), and Australian archaeologists remain active in developing new approaches and methodologies relating to the identification of cultural landscapes and in particular articulating the links between tangible and intangible heritage.

Future Directions

The future for World Heritage in Australia is unclear, along with the role that archaeology might play in any future nomination. There have been repeated calls for a serial rock art nomination incorporating the most significant art sites across the nation. The oldest dated rock art site in Australia (>24,600 years BP) is found in the Laura region of Cape York Peninsula (Cole and Watchman 2005), renowned for its distinctive rock art style which is a major tourist attraction in the region. Unfortunately, management of this area is under-resourced and the Traditional Owners struggle to manage tourism impacts on these sites. Investment in management of these sites has been at best sporadic.

Cape York Peninsula is currently being considered as a cultural landscape created and maintained through the continuing association of the Indigenous Traditional Owners. Similarly, there are Indigenous community calls to renominate the Gondwana Rainforests WHA as cultural landscape. There continues to be an opportunity to develop new models and methodologies to assess, describe, and manage associative cultural landscapes.

It is unlikely that there will be standalone nominations relating to Australia's recent past. In many cases, comparative analysis will show that many such sites are similar to those of other colonial nations. This does not diminish the importance of such sites to the Australian people. They can be effectively protected through local, state, and national mechanisms in most cases. However, it is possible that transnational serial nominations of some of these places would be successful (assuming a future government commitment to support them). One example is the proposal for a transnational nomination of the Cornish mining sites.

The Torres Straits is a region that is not represented in Australia's suite of WH places, and Torres Strait Islander cultural heritage is underrepresented on relevant national and state heritage registers. This is a vibrant cultural landscape which was and continues to be a cultural nexus between Melanesian Papua New Guinea (PNG) and mainland Australia and has deep historic connections through their shared Sahul prehistory.

Australian Archaeological Association Inc. (AAA)

Patrick Faulkner
School of Social Science, The University of Queensland, St Lucia, QLD, Australia

Basic Information

Formally established in 1972, the Australian Archaeological Association Inc. (AAA) has grown to become the largest archaeological organization in Australia (http://www.australianarchaeology.com/). Aimed at encompassing all subfields within the discipline, including Indigenous archaeology, historical and industrial archaeology, ethno-archaeology, and maritime archaeology, the association now represents a diverse membership of professionals from the private, government, tertiary, and museum sectors, students, and others with an interest in archaeology. The association's membership encompasses archaeologists and cultural heritage practitioners (including many Indigenous archaeologists and cultural heritage practitioners) from across Australia and the world and as of 2012 comprises approximately 1000 people.

The AAA holds a conference each year, this being the major national annual meeting of archaeologists, attracting delegates from across Australia and internationally. This conference is hosted by a different institution each year in varying locations across the country to encourage attendance from a broad-cross section of the archaeological community. *Australian Archaeology*, a refereed journal published twice a year since 1974, is the official publication of AAA. In line with the aims of the association, this journal accepts original articles in all fields of archaeology and other subjects relevant to archaeological research and practice in Australia and nearby areas. This includes subject matter covering research and cultural heritage management focused on prehistoric, historic, and contemporary periods.

Through the annual conference, publication of the journal, and the use of various social media platforms, the aims of AAA are to promote the advancement of archaeology, to provide an organization or forum for the discussion and dissemination of archaeological information and ideas, to publicize the need for the study and conservation of archaeological sites and collections, and to increase public awareness of the aims of archaeology in Australia.

Major Impact

Since its inception, AAA has lobbied the Australian federal and state governments, and private industry on behalf of its members, and has prepared submissions on a range of archaeological and cultural heritage-related issues. These

include heritage legislation reform, research funding, and best practice in consulting archaeology (several instances in collaboration with the Australian Association of Consulting Archaeologists Inc. and the Australasian Society for Historical Archaeology).

The AAA actively promotes and supports Indigenous and student engagement with archaeology through the annual conference (often via the provision of funding support for attendance and participation) and promotes the importance of Australia's archaeological heritage as a major sponsor of annual National Archaeology Week events run across the country every year in May. Additionally, the AAA supports and promotes teaching and learning in archaeology across schools and higher education through the Australian National Committee for Archaeology Teaching and Learning (ANCATL).

The association's flagship journal, *Australian Archaeology*, is internationally recognized as a high-quality peer-reviewed forum for the publication of archaeological research from across Australasia. The journal is indexed in the Arts and Humanities Citation Index of the Web of Knowledge, SCOPUS, Australian Public Affairs Information Service (APAIS), and Anthropological Literature and Anthropological Index Online and has been ranked as a tier A journal by the European Reference Index for the Humanities and French Agence d'Evaluation de la Recherche et de l'Enseignement Supérieur.

Australian Archaeology: Pioneers and Traditions

Kylie Lower-Eskelson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Australia's first archaeological observations were made by early explorers and colonists or noted by observers primarily working in other disciplines (Smith and Burke 2007: 1). The first excavation in Australia was undertaken by the governors of the Colony of New South Wales with a focus on human burials (Horton 1991: 3–5), while the first to employ the method of stratigraphic analysis were anthropologists Herbert Hale and Norman Tindale, who undertook archaeological excavations at Devon Downs in 1929 (Hale and Tindale 1930).

Formal archaeological work in Australia began in the 1950s when John Mulvaney returned from courses at Cambridge University and introduced archaeological study into the Australian curriculum (Mulvaney 2011). Mulvaney began work on a number of archaeological excavations around Australia and instructed and mentored a number of students who would become leaders in the field, including Isabel McBryde, Jim Allen, and Ian Glover.

In the 1970s, a series of political circumstances spurred by a confluence between the Aboriginal land rights movement and public environmental concerns led to the creation of state heritage legislation, After this, the amount of archaeological work conducted in Australia dramatically increased, both with development of heritage surveys required by legislation and in academic circles, with several universities opening archaeology departments.

While Australia's first department of archaeology had been instituted at the University of Sydney in 1948, the focus was not specific to Australian archaeology. Later, archaeologists with an Australian focus arrived at the university,

with Vincent Megaw and Richard Wright arriving in 1961 and Rhys Jones in 1963. John Mulvaney was appointed to the History Department University of Melbourne in 1953, later moving to ANU. Isabel McBryde took up the first titled position in Prehistory and Ancient History at the University of New England, Armidale, in 1960, while Jack Golson was appointed to the Anthropology Department at Australian National University in 1961, which was then just moving into the field of archaeology.

Key Issues

Since this time, Australia has grown a thriving discipline covering a range of research topics. The nature and timing of human settlement in the continent has been a long standing topic of interest in Australian archaeology, with the first estimate being made in 1884 by Reverend Peter MacPherson, who postulated an age of 400 years BP for human arrival on the basis of his excavations in Victoria (Horton 1991: 34–43). This date was quickly superseded with the commonly accepted date of human arrival in Australia now being an estimated 50,000 years BP (see Hiscock 2008: 1). The archaeology of the periods of European contact and industrialization has developed into a major field.

The first Australian book dedicated to an overview of archaeological field methods was written in 1983 by Graham Connah (see Connah 1983), which was followed by a more detailed treatment of field methods and related topics by Heather Burke and Claire Smith (see Burke and Smith 2004). The method of ethnographic analogy has often been employed in Australian archaeology and in many cases has served to inform our interpretation of the past (Hiscock 2008: 268–85).

One of Australia's strengths in archaeology has been its analysis of sociopolitical issues, particularly the reflexive analysis of its relationship as a discipline with Aboriginal people (see Burke et al. 1994). This has evolved from simple consultation in the early days to numerous community-based research projects, informed, and sometimes initiated by Indigenous people (Greer et al. 2002). This has begun to transform archaeology in Australia from a field that studied the history of indigenous people to one that cannot only learn more about the past but also benefit contemporary peoples. Employment in cultural heritage management increased dramatically in the early twenty-first century, in response to the legislative requirements of a mining boom in Australia. In 2012, there were over 1000 members of the Australian Archaeological Association.

Australian Association of Consulting Archaeologists Inc. (AACAI)

Fiona Hook
Australian Association of Consulting Archaeologists Inc., Perth, WA, Australia

Basic Information

AACAI Secretariat
PO Box 8382
Armadale, VIC 3143
www.aacai.com.au

The Australian Association of Consulting Archaeologists Inc. (AACAI) was established in the 1970s as an organization for professionals working in all fields of contract and public archaeology. AACAI aims to uphold and promote the discipline of archaeology and to advance the welfare of members. AACAI has a Constitution, a Code of Ethics, and a Consulting with Aboriginal Communities Policy Document. It is affiliated with the Australian Archaeological Association Inc and is a Foundation Member of the Council for the Humanities, Arts and Social Sciences.

Major Impact

The Australian Association of Consulting Archaeologists Inc. is a national organization with local chapters in Queensland, New South Wales, Victoria, South Australia, and Western Australia. The National Executive Committee (NEC) deals with national issues, including membership applications, AACAI policy, and general administration, while State Chapters deal with local matters. AACAI may also provide technical and professional advice, and dispute resolution. It runs an occasional Professional Development Workshop Series. It also publishes a newsletter, a recommended minimum fee scale, and is preparing an Australian Archaeology Consultancy Monograph Series.

The National Executive Committee of AACAI oversees issues of wide-ranging importance for consultants, clients, and the community. The Membership and Publications Committees answer to the NEC. State Chapters of AACAI deal with specific issues relating to practice in different parts of Australia with different jurisdictions and heritage organizational structures. The Chapters hold specialist workshops, seminar series, and act as the first contact point for consultants. Workshops are organized on specialized topics that assist in the professional development of consultants and which help to inform them on issues that affect their work, such as changes to legislation. Recent workshops include the analysis and management of spatial data (GIS applications) and the implications of the GST on business practice and accountability.

AACAI produces a newsletter, which keeps the members and subscribers up to date with a cross section of archaeological issues in Australia and overseas. Each Newsletter includes updates on workshops and lectures of interest to consultants.

AACAI's Register of Consultants lists all Members. For Full Members, the Register lists contact details, academic qualifications, general fields of work (as ratified by the Membership Committee), special fields of expertise, specialist studies, and consulting experience. The Register provides summary contact details, expertise, and availability of Associate Members and lists all Affiliate Members. The AACAI website lists all financial Full Members' details as well as all policy documents. AACAI can serve to lobby collectively on issues deemed to be of interest to its professional membership, such as amendments to heritage legislation. It has formal ties with other archaeological organizations, including the Australian Archaeological Association.

State of Knowledge and Current Debates

Introduction

The first Australians passed through biogeographic filters of the increasingly depauperate islands of Wallacea to enter the most arid continent ever occupied by preindustrial era humans. But were Australia's deserts marginal, extreme, and risky environments for these hyper-adaptive modern humans? We must recall that they were part of a "fast track" southern diaspora of modern humans from Africa to Australia who had already shown extraordinarily adaptive abilities. Given that the Last Glacial Maximum expanded Australia's deserts even further and made for some truly extreme environments, what does archaeology tell us of how Ice Age Australians dealt with the most common environments in Sahul? By the time Europeans arrived in Australia, the deserts were more densely packed with people than ever before, a process that had escalated in the late Holocene to create the renowned desert societies known to ethnographers. Even then, these were some of the lowest density populations ever observed (in some instances one person per 100–200 km^2) (Hiscock 2008). Australian deserts, and desert peoples, have now moved close to the center of Australian society for the first time, providing a vital pump for art and ideas from the desert outward. Here we review Australia's deserts from an archaeological perspective.

Modern humans left Africa between approximately 70,000 years ago (cal BP (years before 1950) is used here to denote calendar years; years BP and BP are used to denote radiocarbon years; ka is used to denote thousands of years ago and generally relates to OSL ages. The Pleistocene period extends from 2 million to c. 10, 000 years ago, and then the Holocene epoch begins) and reached Sahul at the eastern end of this diaspora before 50,000 years ago (Smith 2013). This was an impressive accomplishment, since it entailed crossing through Wallacea, which encompasses the islands of the Lesser Sundas including Flores and Timor, and would have required a series of substantial water crossings out of sight of land (Fig. 1). With the exception of Flores, the archaeological evidence left by the early colonists is indisputably the product of modern human behavior (Balme et al. 2009).

Currently the oldest sites are found in Arnhem Land in the north of the continent. These sites are not far from the coast today but would have been a significant distance inland at the time of first occupation. Dates of between 65,000 and 50,000 BP have been obtained for sediments in association with the lowest stone artifacts recovered at rockshelter sites Malakunanja and Nauwalabila 1 based on the optically stimulated luminescence (OSL) method (Fig. 1). Sites in the inland arid zone such as at Lake Gregory (*Parnkupirti*) have been dated to between 50,000 and 45,000 (Veth et al. 2009). Using the radiocarbon technique that dates charcoal and other organic remains, dates in the order of 50,000–45,000 cal BP have been obtained for sites in both northern and southern Australia (Balme et al. 2009). A spectacular limestone cave in the extreme southwest of Western Australia, Devil's Lair, currently has the oldest radiocarbon date for occupation approximately 48,000 BP (Turney et al. 2001) – to get here would have required passing by, or through, the arid regions of the northwestern reaches of the

Australian Deserts: Extreme Environments in Archaeology, Fig. 1 Map of archaeological sites discussed in text: (1) Malakunanja rockshelter, (2) Nauwalabila rockshelter, (3) Parnkupirti, (4) Devil's Lair rockshelter, (5) Allen's Cave, (6) Cuddie Springs, (7) GRE 8 rockshelter, (8) Madura Cave, (9) Mandu Mandu rockshelter, (10) Riwi rockshelter, (11) Puritjarra rockshelter, (12) Arltunga, and (13) Killalpaninna mission

continent. Thus, while once thought to have been barriers to human occupation until the Holocene, with many analogues to the Great Basin of the USA, desert sites from Australia in the order of 40,000 BP predating glacial aridity are now well established (Hiscock and Wallis 2005; Smith 2013).

Australian deserts are not uniform, and the impact of environmental transformations over time was variable. The deserts exist across a massive belt of semiarid and arid Australia. In the east arid, regions around Lake Eyre contrasted with the large occasionally active river systems such as Cooper Creek. While people such as *Diyari* benefited from rivers, others were suited to more extreme deserts, such as Wangkangurru dwelling in the dune fields of the Simpson Desert. Moving westward, Central Australia is broken by sets of ranges occupied by *Arrandic* speakers, which had long provided a highly elevated refuge at the continent's heart. Further west, the massive Western Desert combines several separate deserts, both sandy and gravel in form. For humans in these environments, such as *Martu* and *Pintupi* peoples, life in the sand-dune country required the use of ephemeral waters and more reliable water in rock holes found in small ranges like the Cleland Hills. Reaching the Western Australian coast, the Pilbara is a vast set of ranges extending from the Western Desert to the arid Indian Ocean coast, now clearly never abandoned at any stage in Australia's past. In the south, the Nullarbor Plain also borders an ocean, the Southern Ocean, abutted by a vast flat, often un-vegetated plain, with little surface water.

The Climate of the Arid Zone

The climatic history of Australia's desert provides a critical frame through which to understand human uses of the arid regions which have witnessed some of the most dynamic human-landscape transformations anywhere (Veth 2005).

The climate of arid Australia is characterized by several drivers, notably the northern summer monsoons, cyclones, and pseudo-monsoons in the north and winter westerlies and frontal systems in the south (Sturman and Tapper 1996). The major river systems that bring rain from the monsoon

Australian Deserts: Extreme Environments in Archaeology, Fig. 2 A summary of paleoclimatic proxies from northern and southern Australia (Fitzsimmons et al. 2012)

belt into the arid interior and fill water bodies such as Lake Gregory, Lake Woods, Lake Eyre, and Lake Frome also play a significant role in the availability of water and thereby accessibility of the desert (Williams et al. 2010). Changes in the strength and location of these systems, therefore, have large influence over the effective precipitation in the arid interior and indirectly affect other hunter-gatherer requirements, including food resources, vegetation, fire regimes, and water availability.

At the time of human arrival, the arid zone was cool but humid, with several of the large lakes (including Lake Frome, Lake Gregory, and Lake Eyre) containing water from intensified summer monsoons and/or an equatorward displacement of the winter westerlies (Fitzsimmons et al. 2012). These conditions, which would have allowed the exploration of much of the arid interior, persisted until the onset of the Last Glacial Maximum (LGM) beginning at ~30,000 years BP and peaking at ~23,000–18,000 years BP.

The LGM in Australia was a period of significant cooling and increased aridity (Fig. 2) and saw a decline in annual temperatures by as much as 10 °C compared with present day; glaciation of uplands in the Snowy Mountains and Tasmania; reduction in rainfall by 60% or more, especially in the interior through the weakening of the summer monsoons and poleward displacement of winter westerlies; changes in vegetation structure to generally more steppe-like and grassland-dominated environments; lower lake levels; increasing dune activity and dust transport; and an expansion of the arid zone into semiarid and mesic environments (Williams et al. 2009; Petherick et al. 2011; Fitzsimmons et al. 2012). Sea levels were also at their lowest through this period, at ~120 m below modern day levels, and led to increased continentality across the interior. In the arid

zone, only the Murray-Darling Basin system showed evidence of continuing resources, being fed by water from the ice fields covering the Snowy Mountains during this period. Fluvial activity at the headwaters of the Cooper River and high lake levels at Lake Lewis, however, suggest episodic wet events occurred within, or on the margins of, the arid zone throughout the LGM.

Following the LGM, the Terminal Pleistocene/Holocene transition saw rapid environmental change. Increasing temperatures initially outpaced precipitation and, at least for prehistoric people, probably led to some of the driest conditions in the last 50,000 years (Markgraf et al. 1992). Sea levels rose rapidly and by 12,000 years BP had reached present-day levels, inundating the continental shelf and likely displacing significant populations in the (now) Timor and Arafura Seas. Lake Carpentaria would similarly be inundated by ~8000 years BP. Recent studies show this period to be one of increasing complexity, with the southern parts of the continent having a brief humid phase between ~17,000–15,000 years BP before increasing aridity at ~14,000–10,000 years BP, while in the north the lapsed monsoon saw dry conditions until after 14,000 years BP after which it got progressively wetter (Fitzsimmons et al. 2012). In the center of Australia, the Todd River reveals evidence of paleo-floods initiating from 14,000 years BP and continuing into the early Holocene (Smith and Ross 2008).

In the early Holocene, ameliorating climate would have allowed far greater access into the arid interior. An area that had generally been fairly inhospitable to long-term occupation now had increasing resources due to an intensification of the monsoon system brought about by the inundation of the Sahul Shelf (Smith 2013). Rainfall from the increased monsoons fed the major rivers systems running into the center of the continent, and Lake Eyre, Lake Frome, and Lake Gregory were, again, all full (Smith et al. 2008).

From approximately 5000 years BP, the current El Niño-Southern Oscillation (ENSO) cycle was initiated (Shulmeister 1999). Beginning as a period of increased effective precipitation and enhancement of the monsoons across Australia, the climate quickly turned to prolonged drying and increased variability. Intensification of ENSO would have caused the movement of the Intertropical Convergence Zone northward, increased the anticyclonic conditions overlying the region, and thereby reduced the likelihood of monsoon or rain-laden low-pressure systems into the Australian interior. Between ~3700 and 2000 BP, this intensification of ENSO caused significantly drier conditions in Australia and increasing climatic variability in the arid interior. A number of different datasets all demonstrate that ENSO, and specifically El Niño events, was consistently stronger and more frequent during this period. However, while the overall effect of ENSO was to reduce rainfall in this period, increasing variability would have seen significant rainfall in the interior occasionally.

The intensification of El Niño events continued and may have increased until approximately 1500 years BP. Several Australian paleoclimatic datasets suggest amelioration from 2000 to 1700 years BP or later. Consequently, the climate of the last 2000 years was considerably more stable than the mid-Holocene, although there were the well-known climate shifts of the wetter Medieval Climatic Anomaly at 1200–800 years BP and the cooler Little Ice Age at 600–200 years BP (Williams et al. 2010).

Regional Trends: Time-Series Analysis

Recent approaches in the use of time-series analysis provide a good opportunity to explore the first-order response of prehistoric people to the climatic changes outlined above. Techniques to explore regional response fall into three main categories: (1) the use of summed probability approaches – involving the compilation of radiocarbon data from archaeological sites as an indicator for population size and/or mobility (Fig. 3a); (2) the interpretation and compilation of individual site records to give an inference of peak occupation periods (Fig. 3b); and (3) artifact z-scores, a standardization approach taken from recent paleofire studies that allows integration of a wide range of spatial and temporal records into one regional curve (Fig. 3c) (Williams 2012).

Australian Deserts: Extreme Environments in Archaeology, Fig. 3 A graph showing proxies for population and/or human activity compared with paleoclimatic records. (**a**) Summed probability distribution (*dashed*) of radiocarbon dates from archaeological sites in the arid zone. Taphonomic correction of the radiocarbon data is also presented (*dark gray line* provides the corrected values with associated 95% confidence intervals (*pale*

As Fig. 3 demonstrates, occupation of the arid zone began soon after colonization. There are now eight sites that would have been located within the expanded arid core of Australia before and during the Last Glacial Maximum. The oldest is *Parnkupirti*, located on a tributary of the once mega-lake of Lake Gregory in the southeastern Kimberley dated from 50 to 45 ka. Lake Gregory itself would have once been a very large freshwater lake fed by the Kimberley ranges to the north and containing shellfish, fish, water fowl, and myriad of fauna such as emu and macropods. Other sites in the Kimberly are dated to 45 ka, while at the western edge of the Central Australian ranges, Puritjarra rockshelter shows evidence for occupation between 40 and 35 ka BP. On the Nullarbor Plain to the south, Allen's Cave has an OSL date of 40 ka, while the earliest occupations at Lake Mungo to the east are estimated by OSL to lie in the range of 50–46 ka. To the northeast, Cuddie Springs dates to 38,500 years ago, while a shelter near Lawn Hill in Queensland (GRE 8) has a radiocarbon determination of 41,500 cal BP (Hiscock 2008; Smith 2013).

Following colonization, human activity and/or prehistoric populations grew slowly until the LGM, when several of the indices show a decline in data. This corresponds with well-documented abandonment of large tracts of the arid interior, population decline, and the falling back of surviving populations into refugia, including the Pilbara, Central Australian ranges, and Murray-Darling Basin (Veth 1989, 2005) (Fig. 4). (It should be noted that the z-score results here are heavily influenced by the Puritjarra rockshelter record, which formed a refugia during this event, and explain the increase in artifact discard during this time.) After a brief recovery, a similar decline in activity is evident during the ACR. Not previously considered in archaeological literature, the ACR probably saw a similar human response as the LGM. With the exception of the LGM and ACR, the data suggests that the Terminal Pleistocene was generally a period of decline or period abandonment in the arid interior.

After the ACR and in tandem with ameliorating climate, significant increases in populations/human activity can be observed in the Terminal Pleistocene/early Holocene between ~12,000 and 8000 years BP (Smith 2013). A significant increase in both radiocarbon data and artifact rates can be observed during this period, and several sites were occupied for the first time (e.g., Puntutjarpa rockshelter in the Musgrave Ranges, Norina Cave and Madura Cave on the Nullarbor Plain, and Marillana A rockshelter in the Pilbara uplands) or contain evidence of intensified occupation (e.g., Allen's Cave on the Nullarbor Plain and Puritjarra rockshelter in the Cleland Hills).

The initiation of ENSO during the late Holocene led to a series of changes in the configuration of Aboriginal populations, between ~4000 and 2000 years BP, including responses inferred as regional abandonment and population decline. During this period, the use of hafting technology, the appearance/proliferation of microlithic tools (e.g., tula adzes and backed blades), and the standardization of stone tools, intensifying long-

Australian Deserts: Extreme Environments in Archaeology, Fig. 3 (continued) gray shading); *black line* presents a 3-point (equivalent to 750-year) moving average. No smoothing or zero trimming was attempted); (**b**) using data from 58 archaeological sites in the arid zone, a graph showing number of occupied archaeological sites by 500-year time intervals (*dashed lined* shows number of sites; *solid line* shows periods of increased artifact discard or other archaeological indices), (**c**) mean z-scores of artifact discard rates (effectively a regional signal) of nine Central Australian rockshelters: Wanmarra, Wanga East (WO4), Ilarari 17, Rrewurlpmurlpme Kweke, Intirekwerle, Urre, Kweyunpe 6, Therreyererte, and Puritjarra. (**d**) EPICA Dome C ice core deuterium/hydrogen ratios – a proxy for temperature, (**e**) sea-level change from sediments in the Red Sea, (**f**) a record of El Niño-Southern Oscillation from an ocean core, SO147-106KL, off the coast of Peru – a proxy for rainfall. Climatic periods are shown, including the Last Glacial Maximum (*LGM*), Antarctic Cold Reversal (*ACR*), mid-Holocene climatic optimum (*MHC*), and intensification of El Niño-Southern Oscillation (*ENSO*). See Williams (2012) for further information and methods presented in this figure

Australian Deserts: Extreme Environments in Archaeology, Fig. 4 Conceptual map of barriers (sand sheets), refuges (uplands), and corridors (interstitial lowlands) used by Aboriginal people during climate perturbations from earliest pluvial phase, expansion of the arid interior during the Last Glacial Maximum, and then subsequent amelioration and climatic fluctuations of the Holocene. Developed by Veth (1989) as a heuristic model to provide a framework for understanding some of the dynamism in the timing, settlement, and mobility of desert societies, this has been supported in large by 25 years of desert studies (cf. Hiscock 2008). The new cryptic refuge model of Smith (2013) sees smaller satellite refugia outside of the major uplands – as deduced from studies of faunal biogeography – especially for persistence of populations during the LGM

distance trade and ritual networks, all occur for the first time (Smith 2013).

After 2000 years BP, hunter-gatherer populations may have increased exponentially, a fact identified by several authors but yet to be adequately explained (Smith and Ross 2008). Importantly, this increase is still prominent in the taphonomically corrected data, indicating it is not an artifact of site loss through time (Williams 2012). This period also saw a series of new adaptive responses to climatic variability, including marked increase in use of marginal and outlying sites, the extended use of existing sites, increased territoriality expressed through greater differentiation of rock art, and more intensive use of lower calorific food resources, such as *Acacia* and grass seed processing. Recent work has shown this period to be increasing complex with human responses to events such as the Medieval Climatic Anomaly (Williams et al. 2010).

Human Response to Extreme Environments

Conditions were generally more favorable when groups entered Sahul c. 50,000 years ago, meaning that people were not entering the daunting and ostensibly "dangerous" landscapes lamented by early European explorers – although this can be in part explained by European lack of familiarity with these environments. These favorable conditions then became more diverse and in many cases challenging by 30,000 BP. This has been labeled the "desert transformation model." In this scenario, groups first adapted to more benign climates and then made changes in their settlement behavior, technology, economy, dietary suites, and material culture to accommodate significant changes in the landscape.

Environmental reconstructions suggest that while conditions would have been colder than today, other factors may have promoted early movement inland. Hiscock and Wallis (2005) make the case that:

> In many regions it is likely that up until 45,000 years ago – and perhaps to 30,000 years ago in some locations – the availability of fresh surface water would have been at least as good, if not better, than during the Holocene. . .The greater relative availability and predictability of resources. . .would have facilitated exploration and exploitation of these unique interior landscapes.

These recent environmental reconstructions, coupled with the patterning of radiocarbon dates and economic evidence from numerous archaeological sites, support a very early movement of people into well-watered inland regions, and here we would argue the "extreme" deserts of Australia.

Groups not only occupied radically different environments in a relatively short period of time; they also began to develop signature regional traits. Interestingly many of these are sources from the then expanded arid zone of Australia. These are inferred from differences in tool production, long-distance exchange networks (witnessed in movement of ochre specimens), complex funerary practices (such as at Lake Mungo at the Willandra Lakes), and very different group-identifying behaviors that have been interpreted from different art styles thought to date to the Pleistocene period (such as the engraved Archaic Faces found from the Pilbara and then in a vast swathe across the western, central, and arid lands on the eastern border).

Lumps of faceted ochre, grindstones on which ochre has been ground, and slabs smeared with ochrous pigment date back to c. 42,000 years ago, from sites in the southwest Kimberley and from a burial site in Lake Mungo, from excavations in Arnhem Land, and from excavations dated to >32,000 BP from Central Australia (Hiscock 2008). It is assumed that ochres were used in the earliest pigment art and that it was likely part of the repertoire of Indigenous Australians (Veth et al. 2011).

Shell beads were important signals of modern behavior in Africa and the Levantine. Representing items of personal adornment and identity, they have now been recovered from Australasia as well. The two key sites of Mandu Mandu Creek rockshelter and Riwi lie on the edge of the deserts of northwest Australia and have yielded "strands" of 22 cone shells older than 32,000 BP and 10 tusk shells dated to approximately 30,000 BP, respectively (Balme and Morse 2006). Such regionally distinct personal wear is seen to have helped in mediating interactions within and between groups.

Long-distance exchange can be inferred from artifacts that lie well outside their supply zone and can be sourced accurately. The oldest comes from a burial site in the Willandra Lakes, more than 40,000 years old, where the closest source for ochre is the Barrier Range some 250 km distant. Ochre as old as 32,000 BP was transported 125 km to the Central Australian site of Puritjarra, while ochres from Mandu Mandu Creek rockshelter in northwestern Australia were transported over 300 km as early as 25,000 BP. Pearl, baler, and tusk shell were moved up to 500 km from as early as 30,000 BP.

During the period of intensified aridity in the Last Glacial Maximum, the ways that humans used the arid zones have been debated. Most agree that certain regions such as inland ranges acted as potential refuges, with other less watered environments being abandoned. This thesis is presented in Peter Veth's (1989) *Islands in the Interior*, where people retreated to ranges in the Pilbara, Flinders, Kimberly, and Central Australia, with the remainder of the arid regions being used in more sustained ways in post-LGM climatic regimes. The main dune fields representing some of the more extreme and challenging environments were thought to remain largely unoccupied prior to 5000 years BP, although some use of sandhill country occurred during the Pleistocene (Smith 1993). The significance of refugia is clear, particularly in the Pleistocene. In building on Veth's paradigm, Smith has recently proposed a model for "cryptic refugia" borrowing from biological studies that suggest that some areas outside of uplands acted as refugia

for scattered populations of various species and that a similar model for scattered human groups may be appropriate. If so, populations would need to survive in smaller numbers spread over a former range, relying on pockets of microhabitats (Smith 2013).

European Contact

Following rare, accidental, and deliberate coastal landfalls in the seventeenth and eighteenth centuries, the arrival of European colonists in Australia in the late eighteenth century heralded a dramatic change from a continent of Indigenous hunter-foraging societies with deep-time attachments to local environments (as they were at the time of contact) to a settler nation wherein migrants vastly outnumbered Indigenous peoples. In terms of world history, Australia is colonized "late," with various colonies (mainly penal in nature) around Australia only after 1788 CE.

Unsurprisingly, Australia's massive interior desert regions remained outside the colonization "frontier" until the mid-nineteenth century. Explorers entered (but did not necessarily survive) the arid lands and encountered the peoples already resident there, although many only saw signs of occupation as they passed by camps and sites. Knowledge was a critical barrier to exploration. Some explorers such as Eyre traveled with Aboriginals, while others such as Canning at times forced Aboriginal people to blaze trails. By the 1860s, explorers had provided knowledge essential for the establishment of isolated outposts strung across Australia's central deserts. These in turn allowed trans-global communication in the form of the Overland Telegraph connecting south-eastern Australian colonies to Darwin, then by submarine cable to Singapore and the British Imperial realms. Another very different communication occurred in and around the telegraph repeater stations for each was established in the traditional country of desert communities – this settings provided the location for significant "early historical" observations about Australian Aboriginal society best reflected in the ethnographic observations of Baldwin Spencer and F. J. Gillen. These and other later observations form the foundation from which ethnographic knowledge of desert societies is constructed (see Keen 2003 for further discussion).

From this time onward, Australia's deserts become the setting for increasingly diverse encounters between Indigenous Australians and outsiders (mainly British, but including other ethnicities to create diverse desert societies located well beyond the colonial "frontier"). Nineteenth- and twentieth-century explorations were fuelled by the desire to access land for stock and suitable droving routes (the Canning Stock Route, e.g., cuts across the Western Desert), imaginary interior water sources (the various permutations of "inland seas"), mineral prospectors (such as the announcement by Harold Lassiter in the 1920s of a centralian goldfield), scientific knowledge, and a place beyond the gaze of colonial authority. Exploration led to the establishment of stock-droving routes that crossed the deserts, linked by water and infrastructure, and to various mineral industries, such as Arltunga in the White Range – Central Australia's first official town following gold discovery in 1887 (Holmes 1989).

The early historical period of Australia's desert, from a European perspective, occurred almost a century after British colonization/invasion. We expect environmental and demographic changes resulting from introduced species to have moved well in advance of colonists (and thus European historical observers). When Europeans arrived, there were few large native fauna and European-introduced species – particularly camels, horses, cows, sheep, goats, dogs, cats, rabbits, and foxes – that had changed the Australian environment dramatically after 1788, resulting in the decline and extinction of many endemic mammalian fauna (Rolls 1984). The ancient Australian soils had never been exposed to hooves, and these animals created havoc (and still continue to) around natural water resources. New plants crowded out native grasses and other plants, at a time when any forms of Indigenous land management – such as the use of fire – were in a state of flux. Few pastoralists looked kindly on the use of fire, seeing it as a threat to stock and the newly installed pastoral infrastructure.

Equally diseases need to be understood – what effect did they have in the early period? Did desert

populations plummet, as has been argued by some? The archaeological record is rarely sensitive enough to rigorously measure fluctuations in population in these critical years, given that it is largely a surface record (Campbell 2002). Certainly, the maintenance of long-distance trade networks as observed in Central Australia, for ochre, *pituri* (native tobacco), grindstones, and ceremonies, suggests some robustness in these desert societies following the disruptive arrival of colonists.

We need to distinguish within the various arid and semiarid environments across the continent whether they were colonized by Europeans and other non-Indigenous peoples or not. Many regions were suitable for sheep and cattle pastoralism – other massive desert regions were simply unviable. A gradient of arability emerged from the margins of semiarid regions where stock could be raised, through to those that could not – a situation exacerbated by environmental degradation and fine climatic variation in the more "extreme" or marginal arid environments.

Another significant element of historical period deserts was the introduction of camels and handlers from various origins in West and South Asia – although widely termed "Afghan" or "Ghan" – a name commemorated in the Alice Springs to Darwin transcontinental railway (Stevens 1989). Little archaeology has yet been done of their camps, places of worship, and work. Equally the arrival of missionaries is a significant archaeological topic, only addressed at a handful of sites such as the Killalpaninna Lutheran Mission on the Birdsville Track (Birmingham and Wilson 2010).

The largest corpus of post-contact archaeological work has been carried out on pastoral sites, some simply interested in pastoralism and others interested in pastoral settings as part of a broader regional process of culture contact. In Lake Eyre, for instance, the archaeological record reveals that Aboriginal people continued to live in and around their estates on vast sheep stations – providing labor, knowledge, and economic security through their seasonal availability. However, only some remained "inside" the pastoral domains, and others remained "outside" as "wild strangers" – at least in the perception of Europeans. Conversely in the northern realms, the demands for work married better with seasonal work demands, with the wet season being a time for the fulfillment of cultural responsibilities (Paterson 2008).

For many today the cultural heritage of deserts reflects pastoralism, remote communities, or survival – or not. Bean (1910) reflected: "There, around Lake Eyre, and over some part of Central Australia you may see them today – deserted homesteads standing out from the desert with the marks of old settlement around them. That is what sheep mean to Australia." The other record of heritage often overlooked is an Indigenous record, which too has historical components.

To summarize, the archaeological study of post-contact deserts can be divided into (1) rural and regional heritage studies interested in buildings, mine, and infrastructure (Gill and Paterson 2007); (2) culture contact between Aboriginal people and various outsiders (Veth et al. 2008), particularly pastoralists; (3) Indigenous responses to historical contingencies, as reflected in subsistence, settlement, depictive traditions (especially rock art) (Taçon et al. 2012), and colonial/government authority and labor demands (Paterson 2008); and (4) "longue duree" approaches that articulate historical events into longer time scales, such as Smith's study of the Cleland Hills (Smith 2005).

In extraordinary events of global relevance, played out locally on patches in the Western Deserts, as late as the 1960s, Aboriginal people who had never seen white people "came out" of the desert and "came into contact" with white Australians for the first time. These events represented the last extreme environments of earth to come into the fold of the wider global community.

Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS): Its Role in Australian Archaeology

Graeme K. Ward
Australian Institute of Aboriginal and Torres Strait Islander Studies, Canberra, ACT, Australia

Introduction and Definition

The statutory authority of the Australian Commonwealth (federal) government known as the "Australian Institute of Aboriginal Studies" from 1964 to 1989 and "The Australian Institute of Aboriginal and Torres Strait Islander Studies" (1989 to present) has as its primary function support of research into Indigenous Australia (Anonymous 1964, 1989). Archaeology was a central focus of the Institute from its inception. The 1961 "Conference on Aboriginal Studies" held under the auspices of the Social Science Research Council that led to the founding of the Institute heard presentations by representatives of each of the disciplines comprising the then fields of Australian Aboriginal Studies: anthropology, human biology, linguistics, prehistory and material culture, and strong arguments for a national research center (Stanner and Sheils 1963; Mulvaney 1963: 33–51; Horton 1986: 83). The Institute's first two principals (chief executive officers), Fred McCarthy (Fig. 1) and Peter Ucko (Figs. 2 and 3), were archaeologists, and chairs of the Institute's Council were involved in prehistoric archaeology Professor Neil W.G. Macintosh (1906–1977), Professor of Anatomy at the University of Sydney and a foundation member of AIAS, between 1966 and 1974; and Professor D. John Mulvaney AO CMG (1925–), known as the "father of Australian archaeology," during the years 1982 and 1984 (Figs. 4 and 5). Most of the first generation of Australian academic archaeologists was involved with the Institute in at least its first decade, guiding not only its activities but also the development in Australia of the discipline itself.

Historical Background

Australian Archaeology Before the Institute

In his address to the 1961 conference, John Mulvaney (1963: 34, 44–5) reviewed the state of Australian archaeology, speaking of the necessity for "typological exactitude," obtaining "more than one age estimation from each site," and of the difficulty of covering the costs of field research. On the same occasion, McCarthy (1963: 53–5) recorded what he saw as the "urgent needs" of Australian archaeology and spoke of the "neglect" of the discipline: there were no university courses in archaeology, no support for research from funding bodies, and neither a

specialist journal nor a professional association to organize regular meetings. There were extremely limited employment opportunities; the few persons active were based in museums. Opportunities for publication were similarly limited; while there had been short articles on archaeology in

Australian anthropological journals and in museum proceedings, Mulvaney's (1961) major review of Australian prehistory had been published in Britain. The only opportunity for disciplinary meetings was at congresses of the Australia and New Zealand Association for the Advancement of Science. There was no legislation in most jurisdictions to protect archaeological sites or to control field research. Australian archaeology was neither professional nor self-sufficient.

The Institute Established: 1961–1964

In December 1961, an Interim Council was appointed to make recommendations toward "the permanent establishment of a national research organisation" (Stanner and Sheils 1963: xiv). In 1964, following the passage of the *Australian Institute of Aboriginal Studies Act* confirming a 22-member Council and a foundation membership of 100, the first principal was appointed. McCarthy (1905–1997) was ethnologist and curator at the Australian Museum in Sydney; while his scholarly pursuits were broad, archaeology and cultural materials studies were central to his interests. He was one of the few archaeologists active in Australia in the previous three decades, known for his systematic excavations of rockshelters in the Sydney area

Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS): Its Role in Australian Archaeology, Fig. 5 John Mulvaney with (L) Dr. Rhys Jones (1941–2001) and Don Ranson at Kutikina Cave, Tasmania, in 1983. John was involved in the successful national heritage listing of the site. Rhys was an early grantee, long-term Member of the Institute and served on its Prehistory Advisory Committee as member and chair for many years as a sometime member of the Institute Council. (Attenbrow and Khan 1994), and for a book on stone tools, for many years the main scholarly work on Australian lithic assemblages (McCarthy 1967/1976). McCarthy, with the assistance of staff initially comprising a secretary, technical officers, and a librarian, commenced building the Institute and establishing its role vis-a-vis other institutions concerned with Australian Aboriginal studies.

Key Issues/Current Debates

Institute Research Grants

The Institute's Interim Council was empowered to provide grants for research, and some of the first went to support archaeological endeavors. The initiative was welcomed; Megaw (1963: 298), acknowledging a fundamental change, noted that "... from the point of view of archaeology in Australia the momentous decision is that of the principle of Government sponsorship for research projects ...". Listing of successful grants in the Institute *Newsletter* effectively publicized the grants process and encouraged further applications at a time when new researchers were being trained in universities.

Twelve of the 63 initial grants in 11 disciplinary categories went to archaeology. By 1968, when McCarthy (*Newsletter* 2(3): 34–6, 38–41) reported assistance for archaeological research, that support was being manifested across the continent, and it was probable that most of the research in Australian prehistoric archaeology was being funded by the Institute and involved not only Australian-based researchers but also archaeologists from Great Britain and the United States. Toward the end of his term as principal, McCarthy (*Newsletter* 3(1): 1–101), summarizing research support during the Institute's first decade, showed that archaeology represented more than one fifth of the total grants for all disciplines and the range of research covered (Table 1).

Major projects supported included excavations at Mount Cameron West, Kow Swamp, and Koonalda Cave; there were also 21 projects to record and research rock art. Funds were provided for films on stone tool manufacture and the Kow Swamp excavations. In the 1970s, with the development of various university departments and State agencies, while archaeology became less dependent upon the Institute, AIAS was still a major source of funding for archaeological research. Toward the end of the next decade, the deputy principal was able to report that a similar proportion of grants had been allocated to archaeology and related fields as had been the case in the 1960s (*Newsletter* n.s.13: 6–21).

Throughout the 1990s, Institute annual reports record that archaeology and related disciplines were substantial recipients of research grant funding. Fifty years after its establishment, despite many changes of emphasis, about one quarter of the Institute's support for external projects in the 2011 grant round was applied to archaeological projects. When the Institute's Grants Program was suspended indefinitely in 2011, the Australian Archaeological Association protested on behalf of its membership.

Support for Publication

An early initiative of the Institute was to provide for the publication of the results of research and related activities. Aside from publishing short archaeological reports in its *Newsletter*, the Institute provided substantial financial contributions toward publication of articles, monographs, books, and technical manuals. The first scholarly article in the *Newsletter* was by archaeologists Megaw and Glover (*Newsletter* 2(3): 4–15); it was accompanied by another on comparison of skeletal materials and a first listing of radiocarbon age determinations. The second principalship,

that of Peter Ucko (1938–2007) who took up his appointment in 1972 from a lectureship in archaeology at University College London where he had been responsible for influential books on European rock art, domestication, and urbanism, coincided with the term of a reforming Australian government, an extension of the Institute's role and fundamental changes in its governance and emphases. In January 1974, Ucko initiated a new series of the *Newsletter*, which subsequently carried an increasing proportion of reports and scholarly articles. The Institute's journal, *Australian Aboriginal Studies*, which replaced the *Newsletter*, was started in 1983 and continues today, albeit in a reduced format less suitable for presentation of archaeological material.

In the 1960s, the institute made contributions to the cost of publication of papers in the existing Australian anthropological journals and various museum series. Publication subsidies were provided also for books, including covering the cost of illustrations for a new edition of McCarthy's *Australian Aboriginal Stone Implements* (1976) and assisting with the publication of McBryde's (1974) New England survey (*Newsletter* 3(1): 38–9). By 1970, however, the Institute had its own publication section responsible for the production of books and audiotapes, as well as the *Newsletter* and annual reports. Various publication series were initiated including manuals and monographs on archaeology and "material culture." The first was the radiocarbon dating manual prepared by Henry Polach and Jack Golson, *Collection of Specimens for Radiocarbon Dating and Interpretation of Results* (1966).

This was followed, over the next decade, by *A Guide to Field Methods and Laboratory Techniques* (Mulvaney 1968); *Aboriginal Antiquities in Australia: Their Nature and Preservation* (edited by McCarthy, Isabel McBryde and Mulvaney 1970); *The Preservation of Australia's Aboriginal Heritage: Report of National Seminar on Aboriginal Antiquities in Australia, May 1972* (edited by Edwards 1975); *Stone Tools as Cultural Markers: Change, Evolution, and Complexity* (edited by Richard Wright 1977); and *Form in Indigenous Art: Schematisation in the Art of Aboriginal Australia and Prehistoric Europe* (edited by Ucko 1977). These works were central to the development of the discipline. From the 1980s, the emphasis of Institute publication changed, notable archaeological exceptions being *A Record in Stone: The Study of Australia's Flaked Stone Artefacts* (Holdaway and Stern 2004) and *The Social Archaeology of Australian Indigenous Societies* (edited by Bruno David, Bryce Barker and Ian J. McNiven 2006).

Support for Positions in Archaeology and Related Disciplines

A major contribution to the discipline was the Institute's funding of positions within museums, universities, and the research program of the Institute itself. In an early example, the Institute sought to provide greater access to radiocarbon analysis and to strengthen the provision of new radiocarbon facilities by paying the salary of an analyst at The Australian National University (ANU). A total of seven professional positions were funded in the 1960s, along with research assistants (eight), technical assistants (two), and State-based research officers (*Newsletter* 3(1): 36–7). This initiative continued during Ucko's principalship, when the Institute funded the establishment of university chairs of archaeology and "material culture," as well as providing for lectureships, usually on the basis of an agreement that the university would continue funding the position at the end of the period of assistance.

In the mid-1970s, Ucko obtained a significant expansion of Federal government funding; he established several research positions based at the Institute. There were to be five research consultants (five-year appointments) and 14 (three-year) research fellowships. Two of the former and two of the latter research positions were in archaeology or related disciplines (*Newsletter* 3: 4–5). An important addition was the appointment in 1974 of a paleoecologist, David Horton, who worked with archaeologists on faunal assemblages (*AIAS Annual Report* 1975 to 1976).

A significant proportion of the Institute's research funding has supported postgraduate positions. Two of the postdoctoral fellows in archaeology in the 1980s, John Beaton and Colin

Pardoe, were based at the Institute; the former adapted the extensive kitchen facilities of the old hostel that housed the Institute to his archaeological laboratory.

Support for Conferences and Specialist Meetings

The 1961 conference provided valuable reviews at that time of the various disciplines of "Aboriginal Studies" (Stanner and Sheils 1963; Horton 1986). It set a useful precedent, encouraging discussions of a wide range of research concerns, and it was followed by other national subject-focused meetings, encouraged and sponsored by the Institute's Council. Institute-supported meetings and conferences were important not only for establishing a collective sense of the discipline of archaeology but also for widening appreciation and agreement on particular matters and sometimes prompting action outside the Institute. In 1963, a "Conference on Nomenclature of Implements and Cultures" was held at the Australian Museum in Sydney (McCarthy 1965). Mulvaney (1986a) wrote that it was the first specialist meeting in Australia of the discipline, Megaw (1963) reported favorably to a wider readership, a subcommittee was established so that the problems raised about typology could be pursued further (*Newsletter* 3(1): 38), and the discussions contributed to the new edition of McCarthy's (1967) manual on the subject, which, decades later, Holdaway and Stern (2004: xiv) could describe as still the ". . .classic typology of Australian stone tools."

Issues of significance to particular disciplines were discussed by members at subsequent biennial General Meetings. In 1964, McCarthy (*Newsletter* 2(1): 3) outlined to the Prehistory Panel his program for encouraging archaeological research toward Australia-wide studies of surface campsites to allow the study of stone tool types in a broader context. At the 1966 General Meeting, discrete disciplinary conferences covered covered human biology, and prehistory and "material culture"; the latter Panel, convened by Mulvaney, explored the need to standardize methods and procedures for recording sites (*Newsletter* 2(4): 49); Mulvaney subsequently edited *Australian Archaeology: A Guide to Field Techniques* (1968; revised 1972; third edition by Connah in 1983).

In 1968, archaeologists combined with ethnographers for a four-day conference on "Monuments and Antiquities: Their Control and Preservation" convened by McCarthy, Robert Edwards, and Mulvaney. McCarthy (1970) described its goal as to place pressure on State and Territory jurisdictions to introduce legislation to protect "Aboriginal antiquities" and to provide for their conservation; the conference proceedings were available several months later (published 1970). At the 1972 General Meeting, a "National Seminar on Aboriginal Antiquities" was convened by Edwards (published 1975) and another by Alan Thorne on "The Settlement of Aboriginal Australia" (*Newsletter* 3(5): 24–5).

The major conference held in conjunction with the 1974 General Meeting was notable for its broad scope, the participation of distinguished international scholars, and some controversy over lack of involvement of Indigenous Australians. The prehistory symposium, "Stone Tools as Cultural Markers: Change, Evolution and Complexity" was published in Canberra and internationally (edited by Wright 1977), as was the symposium on "Form in Indigenous Art" (edited by Ucko 1977). In February 1975, the Institute organized a meeting to discuss computerization of records of collections of Aboriginal artifacts held in State and Territory collections. This was followed by another to discuss problems associated with the export of Aboriginal artifacts; it recommended several actions to control the trade, and the Material Culture Advisory Committee recommended that the Institute help Australian museums purchase objects of national significance that had been refused an export permit (*Newsletter* 5: 15–6). Other biennial conferences followed – the archaeology focus in 1976 was on "Aboriginal artifacts" – but none were on a similar scale and with a comparable commitment to publication of the presentations and resulting discussions as for the 1974 conference.

Seminars have been another important opportunity for Institute researchers and grantees to present the results of their researches. Regular seminars were started by Ucko soon after he

became principal, involving, particularly, Institute-funded grantees who were visiting the Institute, and there were several presentations in the initial series of seminars by archaeological researchers.

Currently, the Institute coordinates two semesters of seminars that occasionally include presentations on archaeology and related topics. Specialist meetings were an integral part of the 1970s Sites of Significance Program, and the Rock Art Protection Program supported conference attendance, especially by Indigenous participants.

Some 32 years after McCarthy's 1963 "Conference on Nomenclature. . .," another meeting, a workshop organized by the Institute and La Trobe University staff members, was held at the Australian Museum (February 1995) with the intention of reviewing McCarthy's typology; a new and comprehensive work on "Australia's Flaked Stone Artefacts" resulted (edited by Holdaway and Stern 2004). Over the last decade, however, specialist meetings have been few and usually held in association with the Institute's major conferences.

The Influence of Institute Committees

In the early 1960s, the Institute used panels of experts for advice on, particularly, the allocation of grant funds; these committees set high standards in the allocation of grants and also guided the development and direction of each of the disciplines. On taking up his appointment as principal in 1972, Ucko developed this concept, enhancing the roles of the disciplinary advisory committees that had previously conducted their business by correspondence. Committee members now meet in Canberra twice each year, not only to advise the Council on grant applications, fellowships, and related matters but also to debate the direction of the development of each discipline and, where necessary, to commission urgent research. Ucko (*Newsletter* 1: 5) emphasized that the task of committees was to formulate research priorities. In 1973, there were 14 committees with up to 12 members each (*Newsletter* 1: 1–4,7). Of relevance here are the Prehistory, and Material culture, Advisory Committees, and the "Committee on Sites of Significance," established under the chairmanship of the deputy principal to oversee the activities of the National Site Recording Program. A few years later, all Institue committees had an additional member in the person of an Indigenous Australian who was working in or who had a particular interest in the relevant field of study. Institute research staff served as "executive officers" for each committee.

The value of the activities of these committees in developing the direction and practice of archaeology in Australia cannot be overemphasized; over the years that the committees were in operation, many senior practitioners were involved in the discussions and deliberations, and the Institute committees were seminal in the development and professionalization of archaeology in Australia. Much earlier, McCarthy had written how the involvement of the principal and members of the Council in making decisions about the allocation of grants gave the Institute a strong role in deciding archaeological research priorities and enhancing professionalism in various disciplines; he claimed (1965: 307) that the Institute was ". . . not only a source of funds for research, but a co-coordinating and advisory body, building up slowly a corpus of information available nowhere else." This process was enhanced by the committee system and may be seen as a major contribution to archaeology and other disciplines of "Aboriginal Studies."

A period of "financial austerity" curtailed the activities of the Institute's committees in the early 1980s (*Newsletter* 17: 4–6), and in 1989, following the passing of the Institute's new Act, most were terminated. A "Research Advisory Committee" including eight elected disciplinary representatives deliberated on grants applications. Some of the wider functions of the Institute's Sites of Significance Committee – which had advised on the allocation of grants under external funding (below) – was superseded by annual meetings of a "National Aboriginal Sites Authorities Committee" hosted in turn by the various State and Territory heritage agencies, involving professional, technical, and Indigenous staff.

Sites of Significance and Rock Art Protection: Externally Funded Programs

The Institute has, on two occasions of significance to Australian archaeology, accepted major external funding to conduct and promote research programs.

Early in his term in office, McCarthy had established a "Catalogue of Aboriginal Relics" to deal with the volume of records being provided by researchers, culled from the literature, and from the voluminous correspondence that he maintained with amateur fieldworkers; copies of the cards were sent to museums and provided the basis of some State site record systems; there was a concern for standardization of terms and recording procedure (*Newsletter* 2(2): 20; 3(5): 26–7). Following the meeting on the need for archaeological legislation at the Institute's 1968 conference, and another on "A National Register of Aboriginal Sites" in 1972, a committee had made recommendations to the Commonwealth government concerning a scheme "to protect and salvage prehistoric monuments and antiquities in Australia." In 1973 – in a period of rapid resource development – funds were provided by the Commonwealth to the Institute for the implementation of a National Site Recording Program (*Newsletter* 3(6): 13): the Institute "... has been vested with responsibility of all sites of either traditional or historic importance to the aboriginal people"; a committee, chaired by the deputy principal, was established with representatives of State and Territory authorities, "one fully initiated Aboriginal man," and others. (In Australia, where responsibility for land tenure rests with the States and Territories, such sensitivities could be mediated by such inclusive membership, but it is not clear how one Indigenous Australian could speak for the many and no doubt various Indigenous interests).

The committee was to meet at least twice each year; it was to formulate a coordinated program and allocate funds to record sites, and a National Register of Sites was to be maintained (*Newsletter* 3(6): 14). Two years later, 22 positions in the various jurisdictions had been filled (*Newsletter* n.s. 3: 11); there were regular meetings of site recorders to discuss processes and other matters of professional interest, a major example being the 1979 site recorders meeting at Kioloa that "...provided an opportunity for site recorders and others, but Aborigines in particular, to meet people currently engaged in research into Australian prehistory" (Dix 1980: 8). There was much to be done, and the expectation that all places of significant heritage value could be recorded was unrealistic.

The Institute continued to provide funding for site recording for several years. By the early 1980s, all Australian States and Territories had archaeological legislation in place and had established their own programs to record and protect Indigenous heritage places with professionally qualified personnel and programs to train and employ Indigenous site recorders. The Sites of Significance Program provided further opportunities for employment of archaeologically trained fieldworkers and thus the development of the field of public or consulting archaeology in Australia, an area in which a substantial proportion of graduates find work. The Australian Association of Consulting Archaeologists, a professional body established in 1979, has 50 full members and more associates and affiliates.

The national Rock Art Protection Program (RAPP) was established at the request of the then Minister for Aboriginal Affairs to provide for the protection of Indigenous Australian rock art. The RAPP was funded by the Commonwealth government for 12 years from 1986, after which time the Institute continued to provide for a similar range of projects for the next decade. The scope of the RAPP ranged from the physical preservation and management of endangered sites, including those threatened by natural elements and by interference from humans and animals, to the support of new research and applied projects including the development of new dating techniques. As with the Sites of Significance Program, it required the cooperation of State and Territory authorities and that of Indigenous knowledge-holders and custodians of the cultural places involved. It has been argued that the program made a significant contribution to the development of systematic studies of Australian rock

and influenced research and practice in these fields elsewhere in the world (Ward 2011).

Indigenous Australian Influences on the Institute and on Australian Archaeology

No Indigenous Australians were present at the 1961 conference; there were, however, many present who had worked in depth with Indigenous communities and would have had their interests in mind (*Newsletter* 1(1): 9–10). In the first decade of the Institute's research activities, there are many instances of the involvement of Aboriginal persons, mainly in association with various grantees, for instance, in bringing traditional knowledge-holders to the Institute to work with researchers. The difficulty that some archaeologists had experienced in obtaining access to sites to conduct their fieldwork was the subject of an Institute meeting in 1971 (Mulvaney 1986b: 105). After the attention brought by the "Eaglehawk and Crow Letter" (signed by Widders and another five activists) on the rationale for the 1974 Biennial Conference and the orientation of the Institute's research program in general, the process of change within the Institute was hastened; along with the opportunities to serve Indigenous interests presented by the *Aboriginal Land Rights (Northern Territory) Act of 1976*, it has been seen as marking "... more or less the start of negotiated anthropology within Australia" (Peterson 1990: 17 fn).

Organizationally, Ucko and the Council encouraged a positive program of "Aboriginalisation" (Ucko 1983; Moser 1995). Indigenous knowledge-holders and community leaders became Members, and, from 1975, an Aboriginal Advisory Committee provided a firmer Aboriginal voice on other committees and in the activities of the Institute in general (*Newsletter* 3: 6). From 1976 a "social issues adviser" participated in the discussions of each advisory committee, so that Indigenous interests could be considered in the various research programs (*Newsletter* 7: 10–1). More Indigenous staff were employed at the Institute, and Indigenous Australians were offered training in research (*Newsletter* 5: 7, 10: 28–9); Indigenous-requested research and training projects were emphasized alongside lists of grants awarded (e.g., *Newsletter* 7: 25). These initiatives were confirmed by a resolution at the 1976 biennial meeting (Newsletter 7: 7). In 1981, outside the Sites of Significance Program, there were ten Indigenous trainees based at the Institute (*Newsletter* 15: 8).

The arrangements for Indigenous participation on the Council and its advisory committees were described as "... the most significant development of all in the 1970s" (*Newsletter* 15: 8). The new direction was formalized by the Institute's revised governing statute (Anonymous 1989); this provided for an Aboriginal-controlled Council with a minority elected component and a disciplinary-based Research Advisory Committee – it was a structure that may been seen as a culmination of the undertakings begun in 1974 toward collaborative governance and research endeavor.

In 1976, there was initiated a category of Aboriginal-requested grants, particularly for the mapping of sites of significance. Concurrently, the Institute continued to provide support through the grants process for the training of Indigenous fieldworkers in site survey and management, despites significant cuts to its budget (*Newsletter* 5: 1–4, 12–3). The new Prehistory Committee decided that its scope should include the ecological studies of living Aboriginal groups (*Newsletter* 1: 7); it reiterated its interest in the investigation of ecological relationships of contemporary Indigenous communities as well as with other archaeological research foci; it discussed ways in which Indigenous Australians might be supported to gain formal qualifications in archaeology (*Newsletter* 11: 11).

Also in the late 1970s, the Sites of Significance Program broadened its scope from archaeological and historic places to include ethnographic places and areas of significance to Indigenous communities – a reflection of the increasing participation in the program of Indigenous fieldworkers. Ucko (*Newsletter* 1: 13) wrote that the program not only reinforced the involvement of the Institute in field research but also that it provided employment opportunities for Indigenous researchers. This had been accomplished through the provision of funds to State and Territory authorities for

Indigenous training programs. The site recorders' meetings had a strong Indigenous involvement.

The archaeology and sites programs, in particular, participated in major changes in direction and emphasis of the Institute's research. When the initial conference and the leadership of Interim Council, then that of McCarthy and his executive and committees, firmly located archaeology within "Aboriginal Studies" it also forged relationships between archaeologists and Indigenous Australians that either had not existed or were at best tentative. These were developed during Ucko's tenure, in conferences, specialist meetings, and in the regular meetings of the disciplinary committees and workshops that they organized. For the year that he left the Institute, Ucko (*Newsletter* 11: 6) emphasized the significant changes in the degree of Indigenous participation in the functions of the Institute.

In the research grants process, applicants were required to demonstrate not only appropriate Indigenous participation but also, through an evaluation by the Research Ethics Committee, appropriate dealing with Indigenous community interests, including cultural and intellectual property rights, and defining procedures for the communication of research results to the communities involved. Jointly initiated applications for projects, those combining Indigenous agendas with technical expertise, tended to have greater chance of success in what had become a highly competitive grants program.

All of this resulted in a growing appreciation both of the depth of Indigenous culture and its legitimacy, on the one hand, and, on the other, of the professional and technical heritage of the discipline and its potential to serve Indigenous aspirations (e.g. McBryde 1985). Archaeologists had to consider Indigenous interpretations of sites and their roles in a wider cultural landscape; concurrently, archaeological results – particularly dating that emphasized the longevity of Indigenous occupation of the continent – quickly became incorporated into Indigenous discourses. As Australian archaeology developed academically and professionally, and beyond the direct involvement with the Institute, it was able to move more readily to an appreciation of broader societal and ethical responsibilities. Places were made for Indigenous students in archaeology; several ANU graduates, for example, work or have worked as consultant archaeologists or in museum research. Not only has research regularly and systematically involved consideration of Indigenous interest and participation but spaces have been made for research initiated and conducted by Indigenous scholars (e.g., Johnston 2009). This process of legitimating and privileging Indigenous voices in archaeology may be seen to have begun in the 1970s at meetings in Canberra.

Future Directions

The Institute was established more than 50 years ago by academics and politicians concerned that much knowledge of the Indigenous cultures of Australia was being lost. Archaeology, one of the founding disciplines, was described as a neglected area of study. Through various avenues, including Institute sponsorship of meetings and conferences, support for specialist committees, for research grants, and for lectureships and chairs, support for publication of research monographs, by encouraging the development of legislation to protect Indigenous cultural heritage places, and insisting on the collaboration with Indigenous communities, the Institute became closely involved in the development and professionalization of archaeology in Australia.

By the turn of the millennium, the role of the Institute in the development of prehistoric archaeology in Australia was muted. The discipline had become a popular university teaching subject with associated research strengths and with its own specialist journals, and with access to various sources of funding; it had its own national association organizing conferences and specialist meetings, encouraging the participation of students in fieldwork and conference activities, and lobbying governments. It constituted a professional discipline with its own institutional base, one largely independent of the Institute. As well, the focus of the Institute itself had changed. It was widely accepted that the traditional disciplines, such as social anthropology, linguistics, and prehistory,

were not necessarily the main sources of knowledge about Indigenous Australian cultures. During his principalship, supported both by the new involvement of Indigenous interests and the acceptance of the research community, Ucko saw the direction of the Institute had fundamentally changed from one of recording knowledge about a past culture to exploring aspects of contemporary peoples. The Institute's governance formally recognized Indigenous interests as did its research agenda; there was a strong emphasis upon collaborative research. Although its grant program continued to be accessed by younger archaeologists, archaeological research was no longer central to the Institute's research and other activities. Archaeology, however, would not have become an independent discipline in the way that it did without the early and continued support of the Institute.

The future is less clear; the continuing reorientation of the Institute's research interests has taken it far from its foundation disciplines including archaeology. The ideal expressed by previous administrations of having staff expertise to maintain a purview of research across the range of Australian Indigenous Studies largely has been forgotten. In parts of the southeast, some community members have revived an understanding of their cultural heritages by drawing upon archaeological research results, but it may well be another generation before there are enough Indigenous Australians who value such research for their own ends for archaeology again to be a central focus of the Institute.

Australian Paleoart

Robert G. Bednarik
International Federation of Rock Art Organizations (IFRAO), Melbourne, VIC, Australia

Introduction

Australia, almost the size of Europe but with a population only a third of that of France or Britain, boasts not only the greatest concentration of rock art in the world but also the highest number of rock art researchers relative to population size. The perhaps most interesting aspect of Australian rock art research is that the country's rock art scholars are significantly less inclined to attempt interpretation of rock art than those of any other world region. Bearing in mind that Australia is universally agreed to have the strongest ethnographic evidence for the original meanings of rock art (Fig. 1), this presents a paradox.

It is the awareness of the uncertainties of etic interpretations that has prompted Australian researchers to opt for scientific investigation in lieu of the creation of a modern mythology about rock art and its meanings. They have therefore been particularly active in such fields as physical rock art analysis, age estimation, survey work, preservation techniques, and methods of site

Australian Paleoart, Fig. 1 Traditional Custodian at Wandjina site he is responsible for, in the Kimberley, NW Australia

management, while interpretation is largely limited to what has been obtained by ethnographic means.

Definition and Historical Background

Paleoart comprises rock art and portable art-like material of preliterate societies. Rock art is basically divided into petroglyphs (made by a *reductive* process, such as pounding, hammering, pecking, engraving, scratching, or finger marking of soft cave deposits) and pictograms (made by an *additive* process, such as painting, drawing, stenciling, or application of beeswax). In contrast to the prehistoric mobiliary art of other continents, that of Australia is limited to just a few types and these remain largely undated.

Similarities between the earliest types of rock art in Australia and southern Asia have suggested that the first colonizers, Middle Paleolithic seafarers from Indonesian islands, brought with them a tradition of creating rock art when they arrived, possibly in the order of 60,000 years ago. A significant part of the surviving Australian rock art, estimated to be in the order of 10% of the total corpus, is thought to be of the Pleistocene. Such age appears to be mostly confined to petroglyphs, as is the case in most parts of the world. Although the presence of Pleistocene rock art has been suggested since the early twentieth century, such antiquity has only been demonstrated since the 1980s. It applies to much of the cave petroglyphs in the southern coastal region and to particularly erosion-resistant rock facies of open-air sites in various parts of the continent.

Australian paleoart has been studied in one way or another since the early nineteenth century, but until the 1980s, its scientific contemplation was sporadic and intermittent. The establishment of the Australian Rock Art Research Association in 1983 led to a significant intensification of research and publishing efforts, and the first world congress in the field, held in Darwin in 1988, prompted the establishment of the International Federation of Rock Art Organizations.

Australian Rock Art

With such a large national corpus of rock art, the creation of inventories is a long-term process involving many individuals and research teams. Because the greatest concentrations of rock art tend to be in the north of the country, this is where much of the survey work has been focused (Fig. 2). The major concentrations are the petroglyphs of the Pilbara, the paintings of the Kimberley and Arnhem Land, and the mixed corpora

Australian Paleoart, Fig. 2 Some important rock art sites and site complexes in Australia: *1* – Murujuga/Dampier, *2* – Depuch Island, *3* – Pilbara, *4* – Spear Hill-Abydos complex, *5* – Tangalma/Carpenters Gap Shelter, *6* – Kimberley complex, *7* – Jinmium, *8* – Ingaladdi, *9* – Laurie Creek, *10* – Kakadu complex, *11* – Puritjarra and Wanga East, *12* – Carbine Creek, *13* – Saxby Waterhole, *14* – Sandy Creek Shelter, *15* – Early Man Shelter, *16* – Walkunder Arch Cave, *17* – Turtle Rock, *18* – Ken's Cave, *19* – Orchestra Shell Cave, *20* – Koonalda Cave, *21* – Pimba, *22* – Devon Downs, *23* – Karlie-ngoinpool, Karake, Prung-kart, Malangine, and Koongine Caves, *24* – Paroong and Yaranda Caves, *25* – Preminghana, *26* – Sundown Point, *27* – Trial Harbour, *28* – Judds Cavern, *29* – New Guinea 2, Cave, *30* – Gnatalia Creek and Waterfall Cave, *31* – Mt. Yengo Rockshelter, *32* – Cobar, *33* – Mutawinji, Sturts Meadows, *34* – Olary-Yunta site complexes, *35* – Flinders Ranges sites

of the Victoria River region and the far north of Queensland (Cape York Peninsula). Noteworthy is also the stencil art centered on the Carnarvon Ranges in Queensland and concentrations in central Australia and eastern South Australia (Flood 1997).

While the sites in the north have attracted the greater interest, comprehensive inventories have been attempted in some southern regions, such as Gariwerd (Grampians mountains) in Victoria, the Olary and Flinders Ranges region of South Australia, in western and coastal New South Wales, and a small selection of petroglyph sites in Tasmania (Sims 1977). It is impossible at this stage to provide reliable quantitative estimates of Australian rock art, and in view of the size of the national recording task, this will remain so for many more years. However, in assembling the best estimates from leading specialists working in the main regions, one would expect that there should be between 100,000 and 200,000 rock art sites in Australia. The largest of them comprise several tens of thousands of motifs, but as a very rough estimate of average numbers, a figure in the order of perhaps 500 motifs per site seems reasonable. Hence, the total number of rock art images is certainly in the tens of millions, roughly half of which are petroglyphs. Pleistocene rock art comprises mostly petroglyphs and consists exclusively of nonfigurative motifs. For the past 100 years, there have been sporadic claims that extinct Pleistocene species or their tracks have

Australian Paleoart, Fig. 3 Gwion Gwion art (inappropriately called "Bradshaw figures"), Kimberley

Australian Paleoart, Fig. 4 Arnhem Land rock art at Nourlangie, painted in 1964

been depicted in Australian rock art, but none of these are scientifically credible.

A number of taxonomies endeavoring to identify stylistic traditions have been proposed, but unless they were very narrowly based, spatially or temporally, they tend to be contradicted by evidence in too many cases. Therefore, no accepted continent-wide stylistic sequence is available, and most traditions, genres, or styles tend to be too heterogeneous for simplistic categorization. Nevertheless, several genres are widely recognized as valid traditions, especially the Wandjina and Gwion Gwion (formerly "Bradshaw"; Fig. 3) painting styles in the Kimberley region, the Woodstock anthropomorphs of the Pilbara, the x-ray paintings of Arnhem Land (Chaloupka 1993) (Fig. 4), the Quinkan figures of Cape York Peninsula (Fig. 5), the stencil traditions

of central Queensland, the widely distributed track and circle petroglyphs of the arid zones, and the early petroglyphs and finger flutings of the limestone caves (Fig. 6). Each of these broadly identified genres features a variety of motifs co-occurring with the characteristic leitmotifs, some of which are thought to be chronologically diagnostic.

Australian Paleoart, Fig. 5 Quinkan rock art, Laura, Cape York Peninsula

Currently the occurrence of authentic cave art has been confirmed in 49 Australian limestone caves, distributed over four regions across the southernmost parts of the mainland and in Tasmania (Bednarik 1990). Most Australian cave art consists of petroglyphs and a significant portion of it is of the Pleistocene, although several genres or styles have been recognized. Six of the Australian caves containing rock art have also yielded evidence of underground chert mining, most of which also seems to date from the Pleistocene.

Analytical Studies

Scientific analytical work began in Australia with the introduction of direct dating and nano-stratigraphy during the 1970s (see Ward and Tuniz 2000 for review). The tradition of rock art dating developed by Australian researchers since then has been instrumental in developing scientific research globally. Nearly all analytical rock art dating methods currently in use were initially developed or introduced in Australia: carbon nuclide and uranium series analysis of carbonates, radiocarbon analysis of oxalates and inclusions in accretive mineral crusts, carbon isotope dating of organic materials in paint residues, luminescence analysis of sand grains in wasp nests, micro-erosion and other weathering indices analyses of petroglyphs, colorimetric analysis of pictograms

Australian Paleoart, Fig. 6 Karake-style petroglyphs on the ceiling of Malangine Cave, Mt. Gambier, which have been minimum dated through uranium-thorium analysis of a concealing reprecipitated calcite skin (speleothem) deposited 28,000 ± 2000 years BP

and patinae, and carbon dating of beeswax figures. Methods introduced elsewhere, such as the determination of cation ratios in rock varnishes or of cosmogenic radiation products, had to be subsequently rejected as unsuitable. Nanostratigraphy, first introduced in the 1970s (Bednarik 1979), has during the 1990s been developed into a stunningly sophisticated technique (Watchman 2000). In one case, ten radiocarbon dates spanning 26,000 years were obtained from a sequence of mineral layers only 2.11 mm thick. This kind of work has been made possible by the introduction of innovative techniques such as focused laser extraction of carbon-bearing substances (Watchman 1993), replacing manual excavation of microscopic stratigraphies.

Analytical work with rock art is not limited to dating attempts, however. For instance, Cole and Watchman (1992) have examined paint residues to locate evidence of binder substances as well as incidental inclusions, such as brush fibers, vegetable remains, pollen, and airborne matter, all of which can provide useful information about the circumstances of the painting event. Other applications of analytical methods developed in Australia include investigations of paint recipes (e.g., Clarke and North 1991; Ridges et al. 2000), "internal analysis" of engravings in deep limestone caves, the differentiation between natural and human rock markings (Bednarik 1994), and the study of petroglyph technology (Bednarik 1998), which includes the analysis of the tools that were used in creating petroglyphs.

The Ethnography of Australian Rock Art

Ethnographic studies of rock art have been conducted by many scholars, providing the world's most comprehensive record of this dimension (Layton 1992). The key message from Australian rock art studies is that unless one is a participant in the culture in question, one has no scientific access to what the rock art means or depicts. Much of rock art "research" outside of Australia comprises such practices and Australian ethnographic rock art research has shown that it has to be rejected. This is the result of observations of the production and use of rock art having been made throughout the twentieth century in some parts of the country and the continuation of the importance of this cultural element within an existing, functioning society. Such research has always shown that the valid interpretations of rock art are vastly more complex than an outside observer would be able to deduce: interpretations concocted by uninitiated outsiders are almost universally false (Macintosh 1977). We know from various contemporary traditional peoples that their perception of the world can differ significantly from that of, for example, modern Europeans, so it would be hasty to assume that people of the distant past perceived the world as any modern group does. Hence it is to be expected that the intricate iconographic meanings of paleoart are not effectively accessible to us.

It is precisely *because* of Australia's superb access to Indigenous ontologies and cosmologies that the continent's rock art researchers have learned to exercise restraint in the invention of interpretative mythologies. Elsewhere in the world the researchers of entirely alien cultures have simply assumed what motifs depict, by projecting their own iconographic perception and contemporary beliefs and mores onto the mute and usually undated rock art. The most important message from Australia is therefore that it is inappropriate to call the simplistic application of alien belief systems to an iconography "research"; it is simply autosuggestion.

Moreover, collaboration between Australian researchers and traditional custodians of rock art sites has shown that other Aboriginal perspectives of rock art can also differ significantly from those of researchers. Archaeology, in particular, has effectively disempowered Aborigines and denied them their identity (Piotrowski and Ross 2011: 38), essentially by posing as the state's interpreter of their past and the gatekeeper of their cultural heritage.

Management and Protection

Australian rock art preservation and site management practices owe much to the efforts of a small number of researchers who have been instrumental in establishing an Australian tradition of site care (Rosenfeld 1985). The underlying strategy is that by selecting well-known and easily accessible

sites for public viewing, attention is drawn to these localities, while the locations of others can and do remain confidential. Vast numbers of sites are on privately owned land, and as many landowners are quite conservation minded, this offers considerable protection, particularly in remote regions. Sites selected for public visitation are usually intensively developed, often with marked access paths, raised walkways and viewing platforms, "psychological barriers" as well as physical barriers of various types, interpretation material, and visitor books. Vandalism by visitors of Australian sites has decreased sharply over recent decades as a result of subtle public education measures (Gale and Jacobs 1986), especially through the mass media. Active conservation measures include graffiti removal, stabilization of deteriorating rock, the installation of artificial drip lines and other changes to hydrology, modification of microclimate, removal of fire hazards, dust suppression, and installation of protective barriers.

Public attitude is itself an important safeguard in rock art protection: it can be more effective than laws, fences, or signs. The change in the public perception of rock art, from one of almost complete indifference and ignorance just a few decades ago to a largely positive attitude, coincides with the establishment and progress of the Australian Rock Art Research Association. AURA has since the mid-1980s successfully lobbied the media and public agencies to promote site protection. Not only have these changes had profound effects on the prospects of Australian rock art to survive, they have had equally significant effects on the public's perception of Aboriginality as such, that is, of the value and relevance of traditional Australian culture.

This shows how far-reaching the results of campaigns to raise the cultural status of rock art can be in some circumstances. In the Australian experience, the public funds made available to conservation programs are in fact quite modest, compared to, for example, those expanded in France. This seems to indicate that the actual level of funding is not necessarily the decisive factor in the success of protection measures for rock art. The most important factor is that such endeavors need to be supported by an altruistic, nongovernmental body such as a scholarly society. State bureaucracies and the mass media can both be usefully enlisted in such efforts, but the impetus must come from dedicated and genuinely motivated individuals with a long-term commitment. Indeed, Australian protective legislation for rock art and other Indigenous heritage resources is both inadequate and can be easily circumvented with the help of compliant archaeological consultants.

This is best illustrated with the most comprehensive Australian campaign to preserve a body of rock art, the campaign to save the one million or so petroglyphs of the Dampier Archipelago, northwestern Australia. They have long been under threat of destruction, both physical and by acidic emissions (Fig. 7), and by 2001 a significant portion of the corpus had been destroyed. The international campaign to save the Dampier rock art has diverted dozens of billions of dollars of industrial development from the threatened sites and secured their listing for National Heritage protection. The International Federation of Rock Art Organizations accomplished this with public support but against sustained opposition from the responsible state agencies, the corporations destroying rock art, and the consulting archaeologists.

Portable Paleoart

In contrast to Australia's rich endowment of rock art, the portable component of the continent's paleoart is surprisingly light. It comprises essentially two forms: cylcons and tjuringa. The first of these, cylindrical-conical objects usually made of sandstone, slate, basalt, or limestone, occur in parts of Queensland and New South Wales. They range in length from 15 cm to over 1 m and in the order of half of them bear some engraved marks. Their purpose is not securely established but among the hypotheses suggested that of a phallic significance is perhaps the most likely.

Although the ethnographic tjuringa (also churinga, atywerrenge, tywerrenge, etc.) are generally made of wood, in the past they were also fashioned from schist or sandstone. Such stone objects were decorated much in the manner of the wooden versions, and they are highly sacred. Access to them is restricted to initiated men, and therefore few researchers who have studied them

Australian Paleoart, Fig. 7 This flame tower of a natural gas processing plant emits 14,000 t of nitrogen oxide per year, which forms nitric acid in the atmosphere. Note the petroglyph panel on the *left*, 400 m from the plant

have published about them. Stone tjuringa are thought to have been made by the Dreamtime ancestors themselves, whereas wooden ones are surrogate replicas of them. It is incorrectly assumed that stone tjuringa, and the complex rituals they engendered, were limited to the Arrernte tribe of central Australia.

A series of Pleistocene limestone plaques found in two caves (Devils Lair and Koonalda Cave) have been described as engraved but in all cases were demonstrated to bear only taphonomic markings. Other materials, such as woodcarvings or paintings, have not survived from early periods and are not considered here.

Current Debates

There have been many proposals over the past 100 years that zoomorphs or animal tracks in Australian rock art are attributable to extinct Pleistocene fauna. Perhaps they were subconsciously inspired by the cave art of southwestern Europe. However, with the exception of the numerous probable depictions of thylacines, both in the form of petroglyphs and paintings, none of these claims have much credibility. The thylacine or Tasmanian wolf only became extinct on the mainland during the late Holocene and in Tasmania in the 1930s. All other animals supposedly represented in Australian rock art are thought to have expired several tens of thousands of years ago. Most of these proposals refer to poorly protected paintings on rapidly eroding sandstone that should not be expected to be more than a very few millennia old. Moreover, the only justification of these claims is that the supposedly diagnostic features of the images suggest the extinct fauna, even though no zoomorphs in Australian rock art are naturalistic, in the sense of resembling textbook images of the species in question. The proponents of these "interpretations" effectively claim that they somehow know which aspects are diagnostic and which are not. For instance, in a recent example, a goose-like image was interpreted as a depiction of Genyornis on the basis of its head shape, and yet only squashed specimens of the species' skull have been recovered. The image was found well outside the known geographical distribution of the species, it had been subjected to rainwater damage, and Genyornis is thought to have died out well over 40,000 years ago. All other claims of this nature are similarly flawed, and there is currently no figurative rock art known in Australia that can be safely attributed to the Pleistocene.

Another issue currently debated in Australia is the relationship of archaeological consultants with

Australian Paleoart, Fig. 8 Petroglyphs at the Spear Hill Complex, eastern Pilbara, with young Aboriginal initiates

their often very powerful corporate clients, particularly when it concerns rock art. The two parties in this debate are people who believe that it is the role of the consultants to facilitate the needs of resource companies at all costs, and those who feel that consultants should be impartial but facilitate the preservation of the cultural heritage resources they investigate. This debate is not endemic to Australia; it can be found in various forms in many countries, but in Australia it tends to be interpreted as a contest of national economic interest or greater good of the nation versus Indigenous heritage, instead of being seen as a confrontation between economic and cultural values. This is because Australia has yet to attain the maturity of a nation that regards its entire cultural heritage as the patrimony of *all* of its inhabitants. In other words, vestiges of cultural apartheid have yet to be overcome in Australia.

International Perspectives

Australian rock art is of interest from an international perspective for several reasons. The amount of sound ethnographic knowledge about its meaning, purpose, production, and cultural roles is significantly greater than anywhere else (Fig. 8). Indeed, in most world regions, there is no such information at all available, and particularly in the endeavors of explaining European paleoart, Australian ethnography has long been recruited for positing bridging analogies. This is ironic because it is precisely the reluctance of Australian rock art scientists to interpret rock art, based on their recognition that etic interpretation is futile in the absence of emic understanding, which distinguishes Australian researchers most from those of the rest of the world.

Another reason to be of special interest is the sheer size of the Australian corpus of rock art, which is to some extent attributable to excellent preservation conditions in a predominantly semiarid environment. Also, Australia has not experienced any significant iconoclasm, which has had much effect in many parts of the world, and much of this rock art is in exceedingly remote parts of the country. The efforts of recent decades to preserve and manage this rock art have contributed as well, and these have also attracted international attention. These practices have been widely replicated in other continents.

Finally, the quality of rock art research being conducted in Australia or by Australian scholars abroad has established scientific standards in recent decades that have international recognition. In recent years, Australian rock art scientists have undertaken work in literally dozens of countries and in all continents. The discipline's preeminent journal, international conference, and organizational structure are all based in this country, and

Australian rock art scientists are frequently consulted internationally.

Future Directions

Protection and management issues encountered with Australian rock art have shown the need to expand the inventory of this vast resource and to attempt creating a comprehensive national register of it. Development projects of various types, especially in the mining and energy industries, are expanding relentlessly into the most remote parts of the country. The safety of the majority of sites, relatively secure until fairly recently, is being increasingly compromised because legislative protection either is inadequate or is being circumvented by exploiting flawed legislation. The most effective remedy to this is to win broad public support for the preservation of Indigenous cultural heritage. This strategy has already been shown to be the most expedient, and it needs to be developed further. In particular, a deliberate effort is required to change the widely held public perception that Aboriginal rock art is the cultural inheritance *only* of the Indigenes. In this sense the rock art can play a significant role in national reconciliation and in facilitating the development of an inclusive attitude to national heritage.

The establishment of a national inventory of rock art is not only required for the purpose of protection and cultural heritage management; it is also of significance to its scientific study. Despite the great efforts that have been made in this direction, the size of the task will involve many more years of recording work. Considering that rock art is being degraded not only though human intervention but also through natural deterioration, this is a task of some urgency and should have precedence over other archaeological work. Future directions therefore demand that greater efforts be focused on endangered rock art, and this would initially involve a change of emphasis in university teaching priorities. This development has already become evident with the recent establishment of facilities at three Australian universities to specialize in rock art studies.

Australian Rock Art

June Ross
University of New England, Armidale, NSW, Australia

Introduction and Definition

The earliest evidence of human occupation on the Australian continent is a piece of faceted red ochre dated to 50–60 ka, recovered from an excavation at Malakunanja II, in the Arnhem Land Region of the tropical north (Fig. 1). While not conclusive evidence for the production of rock art, this and other similar finds indicate that Australia's earliest inhabitants were at the very least processing pigment. Hampered by difficulties in dating rock art assemblages and the limited potential for the preservation of rock art of such great antiquity, identification of the earliest rock art remains a challenging goal for Australian researchers.

Australia is the world's smallest and driest, permanently inhabited continent with an area of about 7.6 million square kilometers. The geographic location of the continent and its size mean that it encompasses a wide range of climate zones. The climate along the southeastern margins of the mainland and island Tasmania is classified as temperate. In the north, tropical climates are marked by hot summers and heavy monsoonal rains, while the climate of the vast interior covering almost two thirds of the continent is arid or semiarid and is characterized by low and unpredictable rainfall. Rock art is found in all climatic zones from the highest snow-covered mountain ranges in the southeast to the vast sand-ridge deserts of the center and the rugged and remote gorges and coastal islands of the north and northwest (Fig. 1).

In northern, central, and western regions of Australia, rock art remains an integral part of Aboriginal culture and belief systems. Although varying in form and detail across the country, the concept of "the Dreaming" is a universally held philosophy that spells out the relationship between Ancestral Beings who created the land, Aboriginal people, and nature (Berndt and Berndt 1988). Aspects of the Dreaming are manifested in rock art throughout Australia, and the origin of many paintings and engravings is attributed to the creation period or Dreamtime. While new assemblages are rarely created today, remarking or other practices that involve traditional maintenance of the potency of rock art sites continue where sites are accessible to communities, now often located in distant towns. In other regions where European colonization has resulted in dislocation of people from traditional lands, specific knowledge of the meaning and function of rock art assemblages has been lost, although the significance of the rock art remains integral to today's custodians.

The richness of Aboriginal life and the variability of cultural practices across the country have been captured in numerous ethnographic records collected in the nineteenth and early twentieth centuries by researchers such as R. H. Mathews, B. Spencer and F. Gillen, W. Roth, H. Basedow, J. R. B. Love, D. S. Davidson, A. P. Elkin, and T. G. H. Strehlow and more recently by C. and R. Berndt, C. Mountford and R.A. Gould, N. Munn, H. Morphy, R. Layton, I. Crawford, and V. Blundell. The complexity of rock art as a symbolic system, alongside the multivalent meanings attributed to single motifs recorded in these ethnographies, has warned rock art researchers of the futility of relying on literal interpretations of individual motifs alone, a point made strongly by academics, John Clegg (1991) and Iain Davidson (1997). Similarly, the

Australian Rock Art, Fig. 1 Australian rock art provinces. (Modified from Layton 1992)

use of simple ethnographic analogy to explain the content or composition of assemblages across regions is acknowledged as problematic. In addition, running contrary to earlier cultural evolutionary ideas that saw Aboriginal people living a substantially unchanged life over thousands of years, the archaeological record attests to the dynamic nature of Aboriginal society especially through the Holocene. To a large degree, these factors have directed Australian rock art research away from speculative interpretation of the meaning of motifs towards research questions that seek to develop an understanding of the role that rock art played in social organization, economies, and ideologies through time.

There are more than 100,000 recorded rock art sites in Australia with many more being added to databases held by universities and state government agencies each year. Rock art is typically found in rockshelters, along cliff lines, on open rock platforms, in gorges, or on angular boulders forming low hills rather than in deep caves. In arid regions where water is scarce, rock art sites are associated with water supplies however meagre. Most techniques including petroglyphs (produced by pecking, abrading, incising, or pounding) and pigment art (pictographs: incorporating painting, stencilling, printing, and drawing) are found in all major art provinces in varying proportions. Motifs created with beeswax pellets have a limited

Australian Rock Art, Fig. 2 Typical Central Australian engravings. (Photo by June Ross)

distribution in the north. Studies show that geological substrates alone do not govern the selection of technique used to create rock art assemblages but rather choice of technique can be attributed to regional, temporal conventions. For example, engravings have been produced on the relatively soft Hermannsburg sandstones of Central Australia but are also found on the extremely hard and dense gabbros and granophyres of the Pilbara in the west. Extensive panels of engraved art produced on open rock surfaces dominate the assemblage recorded throughout the central and southern arid zones, while in the northern regions of Cape York, Arnhem Land, Victoria River District, and the Kimberley, rock art painted on shelter walls is most common. On friable white sandstone in the Central Queensland Highlands, stencilling is the most commonly documented technique, whereas on the Woronora Plateau south of Sydney, drawings predominate on similarly light-colored sandstones. In most art provinces, a variety of techniques occur together although specific techniques may dominate during different time periods: the Sydney region stands out as one where two different art media were practiced contemporaneously (McDonald 2008). At the Kuyunba rock art complex in Central Australia, more recent assemblages of drawing, printing, pounding, abrading, and scratching have been recorded in addition to production methods used to create earlier assemblages, i.e., engraving, painting, and stencilling.

Space precludes a comprehensive overview and detailed descriptions of the rock art from each style province and the changes that took place through time. Very briefly, the rock art of the Central Desert region is dominated by engraved assemblages with a limited graphic vocabulary dominated by circle variants, animal tracks especially bird and kangaroo tracks, lines, arcs, mazes, dots, and pits (Fig. 2). Believed to have its origin in the Pleistocene, the same suite of motifs continued to be produced in the more recent painted assemblage and is retained today in Western Desert acrylic paintings produced for a national and international art market. In contrast, engraved rock art from the Western Desert and Pilbara regions, some of which is also thought to be of great antiquity, is dominated by depictions of animals especially kangaroos (Fig. 3), birds, and marine species such as fish, turtle, and anthropomorphic figures. Most striking are a series of intaglio faces now labelled archaic faces that are found throughout arid regions across the continent (McDonald 2005).

The rock art of Arnhem Land and the Kimberley regions is dominated by painted assemblages with marked stylistic changes through time. Across both regions, pecked cupules, grass prints, large naturalistic figures, and hand stencils were replaced by elegant, monochrome anthropomorphic figures decorated with an array of tassels, aprons, headdresses, and other accoutrements: known as dynamic figures in Arnhem Land and

Australian Rock Art, Fig. 3 Macropod engraving from the Dampier Archipelago. (Photo by Ken Mulvaney)

Gwion figures across the Kimberley where they appear in a highly decorated form (Fig. 4). Assemblages in both regions also have accurate depictions of animals from their respective regions. Differences between the arts of the two regions become marked in the more recent art assemblages. In Arnhem Land, polychrome X-ray figures display not only the profile of the animal or anthropomorphic figure but also the internal organs and/or skeleton. Over the last 3,000 years in the Kimberley, large spirit figures called Wanjinas were painted on rockshelter walls. Wanjinas are known by individual names and stories of their exploits in the Dreamtime continue to be passed on to younger generations. Often many meters long, these are painted in red, black, and sometimes yellow on a prepared white background and feature two large black eyes, a halo-type headdress, but no mouth.

Australian Rock Art, Fig. 4 Gwion figures, Kimberley. (Photo by June Ross)

Historical Background

Prior to the 1970s, Australian rock art studies generally involved description and quantification of assemblages. This resulted in detailed documentation of sites such as those recorded by Fred McCarthy on Groote Eylandt, Dupuch Island, Port Hedland, and the Cobar Pediplain; Ian Crawford in the Kimberley; Robert Edwards in the Olary and Central Desert regions; and B. S. Wright in the Pilbara. Based on these early

descriptions, several researchers (D.S. Davidson, F. McCarthy, C. P. Mountford) proposed pan-Australian rock art sequences constructed around motif classification and geographic distribution. However, it was the evolutionary stylistic sequence proposed by Lesley Maynard (1979) – and her archaeological approach to art assemblages – that influenced much of the later thinking related to regional styles and stylistic distribution.

The 1970s saw a dramatic increase in Australian rock art studies driven by the arrival of a number of overseas researchers with international reputations (e.g., Peter Ucko, Andrée Rosenfeld, and Patricia Vinnicombe). For the first time, Australian universities offered specialist units in rock art studies within archaeology degrees at ANU (Andrée Rosenfeld and Howard Morphy) and Sydney University (John Clegg) and later at UNE (Mike Morwood and Iain Davidson). This stimulated a proliferation of regional studies in the following decades, for example, Bruno David in the North Queensland Highlands and with Josephine Flood in the Victoria River District; Paul Taçon and Darrell Lewis in Arnhem Land; Andrée Rosenfeld in Central Australia and Cape York where Mike Morwood and Noelene Cole also worked; Pat Vinnicombe in the Sydney Basin, Kimberley, and Pilbara; Michel Lorblanchet at Skew Valley; Claire Smith in Jawoyn country in southern Arnhem Land; Iain Davidson and June Ross in northwest central Queensland; and Jo McDonald and John Clegg in both the Sydney Basin and western New South Wales. More recent regional studies have been undertaken by Ken Mulvaney in the Dampier Archipelago, ben Gunn and June Ross in the Central Desert; Jo McDonald and Peter Veth in the Dampier Archipelago and Western and Great Sandy Deserts; Paul Taçon in the Wollemi and Kakadu National Park; Sally May, Chris Chippindale, Bruno David, Bryce Barker, Daryl Wesley, and ben Gunn in Arnhem Land; Liam Brady and Bruno David in the Torres Strait; Julie Dibden and Jillian Huntley in the Woronora Plateau; Al Paterson in the Pilbara; and Mike Morwood and June Ross in the Kimberley.

Running parallel to these studies, important groundwork was laid by dedicated individual researchers such as Percy Trezise in Cape York, Eric Brandl and George Chaloupka (1993) in Arnhem Land, and Grahame Walsh and David Welch in the Kimberley. Relative stylistic chronologies in each of these regions are underpinned by the extensive fieldwork, careful documentation, and analysis of rock art over many decades by these committed enthusiasts.

The dynamics of the 1980s can be attributed to two significant influences. First, the archaeological milieu in which rock art was taught encouraged students to think of rock art as an archaeological dataset to be studied by formal methods. From this time, most major rock art projects were undertaken as part of collaborative research projects involving excavation as well as disciplines such as paleofaunal and paleobotanical studies, which provided social and environmental contexts against which to set an understanding of art assemblages. Datasets were routinely analyzed using statistical analyses including cluster analysis and principal component analysis.

However, by far the most influential changes to the way rock art was perceived resulted from the introduction of new international theoretic approaches that complemented archaeological methods being fostered in Australia. Interest shifted from the concept of art as an object in its own right to a focus on rock art created by the intentional actions of humans in the past. The particular way of producing the art, the "style" was viewed as a means of communication. As Martin Wobst argued, art assemblages can encode a range of social, economic, and ritual information. Conceived in this way, the form and structure of assemblages could thus be seen to express group interaction or differentiation, social boundaries or social organization.

This notion was extended by Clive Gamble, based on ethnographic information from Australia's deserts. He saw a corresponding relationship between the form of art assemblages, the type of social networks people utilized in the past, and availability of resources. Areas with poor resources would have homogeneous art assemblages over vast areas indicating open social networks, while conversely, resource-rich areas

would have heterogeneous art styles, each distinctly different from its neighbors, corresponding with closed social networks and territoriality. Open social networks are seen as a means to allow flexibility and mobility in areas subject to unpredictable climates. The theory of information exchange has been widely adopted as an explanatory tool for diachronic changes in the content and composition of rock art assemblages found across the Australian continent. For example, Mike Morwood identified tightening of social networks and a corresponding change in the composition of the rock art assemblages across the Central Queensland Highlands around 3,000 years ago (2002).

The theory that Polly Weissner popularized, "identification via comparison," where each individual or group understands their place in the world by comparing aspects of their material culture with others has been similarly influential in Australia. In the case of rock art, people could choose to produce art that was stylistically similar to others to cement their group status, or conversely, they could choose to differentiate themselves by producing singular art assemblages. Using rock art or material culture in this way, people in the past could mediate their interactions with others. As Australian Aborigines were hunter-gatherers, regularly moving across the landscape, rock art provided an ideal tool to flag identity and mediate predictable interaction in their absence. Ross et al. (2008) have argued that the production of distinctive anthropomorphic figures within a bounded area in northwest central Queensland provided a mechanism that bonded local inhabitants while at the same time flagging to outsiders coming into the area to trade that they needed to mediate their behavior in some way (Fig. 5).

Australian Rock Art, Fig. 5 Anthropomorphic motif, Northwest Central Queensland. (Photo by June Ross)

Ceremonial gatherings involving large aggregations of people from distant locations are well documented in Australian ethnographies. Meg Conkey identified the structure of graphic elements on bone artifacts, which she contended enabled her to trace the history of aggregation at sites in Northern Spain. Identification of similar structural criteria, particularly richness and diversity in the rock art assemblage at sites within the Australian arid zone, has provided a means to distinguish aggregation sites in the absence of ethnographic evidence. Jo McDonald and Peter Veth (2012) attributed the stylistic diversity in rock art assemblages in the Western Desert to the aggregation of people from different groups across the region. Brett Galt-Smith tested the identification of aggregation sites based on Conkey's criteria against assemblages from sites known to have been the focus of large ceremonial gatherings during the late nineteenth century in Central Australia. He found that Conkey's criteria were useful markers of large aggregation but were less successful in identifying more localized aggregations.

There has been resistance in Australia to one international interpretive framework. Shamanism and the associated altered states of consciousness espoused by David Lewis-Williams as an explanation for the production and form of rock art assemblages in South Africa, Europe, and other parts of the world have not been widely adopted by researchers in Australia, largely because there

is no ethnographic evidence for shamanism within Australia. Although ethnographies recount some instances where altered states of consciousness might have been achieved – when performers accompanied ceremonial activities with long periods of rhythmic beating using clapsticks or when young men endured periods of fasting during initiation – none records any association between these activities and the production or content of rock art.

The establishment of an Australian rock art organization and the passing of heritage and environmental legislation have also contributed to the direction and growth of rock art studies in Australia. In 1984, the Australian Rock Art Association (AURA) was launched by Robert Bednarik. Conferences organized under the auspices of AURA have drawn international researchers to Australia, and the publication of its biannual journal provides a forum for dissemination and discussion of the results of both national and international rock art studies.

Political change and the promotion of ethical considerations and recognition of Indigenous ownership and intellectual property have also influenced the path of rock art studies in Australia. Today, most rock art projects are run in collaboration with Aboriginal or Torres Strait Islander owners who now participate in research as active partners with their own agendas and priorities. Many work as rangers managing rock art or other cultural heritage sites on their country, while others have developed tourist programs aimed at educating visitors about the Indigenous significance of sites.

Key Issues and Current Debates

Reliable chronometric dating of assemblages remains central to the research efforts in Australian rock art. The longevity of rock art production across the continent is signalled not only by the extreme weathering of some engraved assemblages but also by the marked stylistic changes identified in many regional rock art provinces as well as the presence of ochre crayons in excavated sediments dating back from the recent past to the time when the original occupants arrived on the continent. Despite concentrated efforts, attempts to date rock art have met with limited success.

David et al. (2013) have reviewed the evidence for establishing the age of ancient pictographs in Australia and note that few proposed dates involve direct and reliable dating of identifiable rock art motifs. Rather, early dated examples include pigments only seen in cross section sandwiched between gypsum-oxalate crusts, the problem being that the very mineral skins that provide a substance to date also obscure the art. The use of radiocarbon dating on other organic materials as a means to date pictographs has met with mixed results. It has been used to successfully date wax motifs, the earliest of these from a turtle motif in Arnhem Land and dated to around 4,500 BP. Samples from a single charcoal drawing located in the Sydney Basin provided two vastly different ages, a problem likely to have resulted from substrate contamination. The radiocarbon dating of charcoal ash adhered to the bottom of a stone slab painted with a partial black motif provides the oldest date (28,000 BP) for Australian rock art although the motif is unclear. More contentious has been the minimum date of approximately 17,500 BP proposed for a Northern Kimberley Gwion figure and hand stencil obtained by Bert Roberts from an overlying mud wasp nest using optically stimulated luminescence. Criticism has been directed towards the technique, but most disquiet results from concerns about the relationship of the section of the nest being dated to the underlying figures (Aubert 2012). Additional concerns were raised when dating of oxalate skins by Alan Watchman indicated a mid-Holocene date for the same stylistic period.

Continued improvements in the preparation and extraction processes for radiocarbon sampling such as plasma oxidation and accelerator mass spectrometry have been used to date charcoal drawings and organics within pigment. Results have provided a range of dates for late Holocene assemblages in the Western Desert, Arnhem Land, and the Kimberley enabling researchers to build temporal frameworks for the dynamic changes that occurred in the last few thousand years. Uranium series, a dating technique used successfully by Maxime Aubert in China and East Timor, is

now being trialled in the Kimberley at locations where art is beneath a covering of precipitated flowstone. Even with ongoing improvements to dating techniques, Rosenfeld and Smith (1997) argue for the continued importance of developing a fine-grained understanding of relative stylistic sequences to complement and inform dating projects. Chippindale and Taçon (1998) provide a comprehensive summary of methods that can be adopted to develop such sequences in Australia.

Researchers seeking to date engravings in the past had to rely on recovering examples from stratified deposits. Andrée Rosenfeld dated deposits associated with engravings excavated from the Early Man Shelter in Cape York to about 14,000 BP. Today, dating techniques focus on establishing ages for mineral coatings covering engravings such as silica skins, calcium oxalate crusts, rock varnish, and localized calcium carbonate deposits, thus providing a minimum date for the underlying art. After a promising start, cation-ratio dating of rock varnish has proved unreliable, and likewise, the dating of carbonate deposits has met with little success. Outcomes from Alan Watchman's radiocarbon dating of oxalate crusts have provided more convincing results. Crusts overlying pecked cupules in the East Kimberley provided age estimates up to 5,840 years old, while the dating of crusts overlying similar suites of rock art at two different sites in Central Australia returned to mid-Holocene dates (Smith et al. 2009). The latter example provided a means of validating Watchman's results. The rock art had been engraved on slabs of roof-fall lying on shelter deposits. Radiocarbon dates were obtained from deposits immediately under the slabs of roof-fall providing a maximum age for the engravings thus bracketing the age of the art between maximum and minimum ages obtained using two different techniques.

Dating studies are now being augmented by analyses of the chemical and mineral composition of pigments and ochres to provide information on the composition of paints and the origin of pigments. Further, a detailed understanding of the composition of pigments provides data that can inform management decisions relating to conservation of art for future generations. The chemical fingerprint of paint samples can be established in the field in situ using portable X-ray fluorescence without damage to the art although Jillian Huntley's research flags some limitations to this technique (Huntley 2012). Alternatively, samples are removed and then processed and analyzed under laboratory conditions.

Interest in gestural marks or associated rock art traditions has continued to grow in Australia as the role and significance of these marks become more apparent. The process of interacting with rock surface continues to retain its significance for traditional owners in some regions although rubbing with a hand frequently replaces earlier practices. While assemblages of pecked cupules and abraded grooves have been regularly recorded in the past, few have been quantified or subjected to rigorous analysis. The recording of abraded areas, battered and flaked edges and random pecking on, or associated with art panels has largely been neglected. Studies on flaked edges at rock art sites in the Northern Kimberley are currently underway in an effort to establish if this practice had a ritual or economic function.

A range of other key issues are currently under debate. Speculations dating to the late nineteenth century that extinct megafauna or their tracks had been depicted in Australian rock art have been revived, although these assertions are not universally accepted. Over recent years, claims have been made for a range of painted motifs judged to be iconic depictions of *Genyornis, Zaglossus, Palorchestes*, *Diprotodon* and *Thylacoleo*, taxa deemed to have become extinct on the Australian continent around 40,000 years ago. Identifications rely either on the likeness of the motifs to hypothetical reconstructions of extinct fauna or on the comparative size of the depictions considered to be larger than any related taxa present today. Further, the presence of depictions of megafauna has been used by some researchers as a temporal proxy to extend their chronological framework and underpin relative sequences.

Bruno David (2002) has argued that both Aborigines and other Australians see the Dreaming as atemporal. Yet when he examined the archaeological manifestations of the Dreaming as we know it from ethnographic times, he concluded that the evidence from multiple sites across Australia reveals a dynamic and emergent culture

rather than an unchanging one or even one of great antiquity. This has implications for the understanding of the decline or cessation of earlier art styles and the rise of distinctive regional rock art assemblages that appeared during the late Holocene.

By the time of European contact, Australia was a continent of Aboriginal nations, each with its own language, ceremonial practices, and rock art style. Earlier more homogeneous rock art styles produced over vast areas were replaced with differing regional styles. Identification of the forces responsible for driving changes in rock art assemblages has been the focus of rock art studies in many regions, with available datasets or theoretical perspectives influencing conclusions. In the late 1960s, researchers hypothesized that the demise of the production of elegant monochrome Gwion figures (formerly known as Bradshaw figures) and the later emergence of polychrome Wanjina-style figures over the past few thousand years resulted from the diffusion of ideas from a new wave of immigrants from Southeast Asia. In Arnhem Land, researchers identified dramatic changes in the topography of the region resulting from fluctuating sea levels and an increase in population density supported by resources from the rich alluvial plains that formed (Taçon 1989). Estuarine species depicted in earlier rock art such as mullet and saltwater crocodiles were replaced by paintings of freshwater species such as magpie geese and water lilies. In Central Australia, the change from a relatively homogeneous engraved assemblage to dramatic site-specific motifs produced during the last 1500 years was attributed to changes in social organization necessitated by pressures from increased population resulting from the onset of more productive but unpredictable climates.

Contact rock art is now regarded as an important Indigenous archive. Clarke and Frederick (2006) demonstrate in their detailed study of recent rock art on Groote Eylandt that analysis of the content and form of the motifs as well as the social, geographic, and historical contexts of contact rock art can be used to examine the complexity of relationships, meanings, representations, and exchanges that resulted from cross-cultural interaction between Aboriginal people and newcomers. This view is supported by the findings of Paul Taçon and Sally May (Arnhem Land), June Ross and Ursula Frederick (Central Australia), Alastair Paterson (Pilbara), Jo McDonald (Sydney Basin), Noelene Cole (Cape York), and Liam Brady (Torres Strait) in their analyses of contact rock art. The history of contact and cross-cultural exchange varied across regions between rural, town, and mining settlements, but analysis of contact rock art assemblages demonstrates that Aboriginal people should more accurately be viewed as keen observers and active participants in past cross-cultural exchange rather than simply as passive victims.

While the threat to rock art assemblages posed by the mining boom of the last decade has led to an increased awareness of conservation and management issues associated with the preservation of sites, direct government financial support for specific rock art management programs and heritage agencies has been reduced. However, the proportion of government funds channelled through the Australian Research Council has seen a far greater proportion of available grant money being awarded to archaeological projects with strong rock art components. In threatened areas, rock art recording and management strategies are generally completed as consultancies commissioned by resource companies or as negotiated offset arrangements where resource companies fund research to better understand the resource generally.

There is a marked trend today, for rock art to be included as a major component in large regional archaeological projects in Australia. Neither is it unusual for projects to incorporate multiple proxies from varied scientific disciplines in order to formulate the clearest picture of the past. The range of disciplines associated with projects such as *Lifeways of the First Australians* in the Southern Kimberley, *Change and Continuity* in the Northwest Kimberley, the *Canning Stock Route: Rock Art and Jukurrpa Project* in the Western Desert, or *Connecting Country: The Jawoyn Homeland Project* in Southern Arnhem Land is more diverse than ever before. Rock art researchers now work side by side with geomorphologists; geochronologists; physical geographers;

anthropologists; historians; geologists; palynologists; ecologists; faunal, botanical, ochre, and shell experts; GIS specialists; photographers with specialist technical skills; and filmmakers, each providing ever more specialized knowledge.

Future Directions

In the past decade, three university rock art centers have been established: the Australian National University's *Rock Art Research Centre* in Canberra founded under the guidance of Howard Morphy, Griffith University's *Place, Evolution and Rock Art Heritage Unit* led by Director Paul Taçon and situated on the Queensland Gold Coast, and the University of Western Australia's Perth *Centre for Rock Art Research + Management* with Jo McDonald as Director. Initiatives instigated by these fledgling bodies include raising the awareness of heritage and rock art management issues amongst government agencies and the general population, facilitating and broadening the scope and relevance of rock art research, funding of visiting international scholars, organizing professional workshops, providing worldwide access to remote rock art sites via internet forums such as Google, and dramatically increasing the number of students studying rock art at tertiary level across Australia. The amount of industry and institutional funds committed to these centers attests to the significance of role that rock art is seen to play in Australians' past, present, and future.

Australopithecines

Ronald J. Clarke
Evolutionary Studies Institute, University of the Witwatersrand, Johannesburg, South Africa

Introduction

The term "australopithecines" derives from the subfamily name Australopithecinae that was first used by Gregory and Hellman (1938). It differentiated the ape-men *Australopithecus* and *Paranthropus* from the subfamily Homininae or humans that included the genera *Homo* and *Pithecanthropus* and which are abbreviated to "hominines."

Australopithecines are known from Plio-Pleistocene sites in South and East Africa and in Chad. Claims for their presence at sites outside of Africa have not been confirmed. Australopithecines have over the years been variously referred to as ape-men, man apes, near-men, or Dartians after Raymond Dart who named *Australopithecus* in 1925. These names reflect the characteristics of the Australopithecines as being manlike primates with apelike features.

Key Issues/Current Debates

The first known Australopithecine was blasted out of a limestone tufa cliff at Buxton Limeworks near Taung, South Africa, in 1924. A natural endocranial cast and a block of calcified matrix displaying sections of cranium and mandible were, with other fossils, saved by miner M. de Bruyn and taken to the mine manager's office. Later, they were sent by geologist R. B. Young to Professor Raymond Dart who had asked Young to look out for monkey fossils. Dart found that the natural brain cast fit into some exposed bone in the matrix block. After he had cleaned away the hard matrix, he realized that he had the face and brain cast of a primate that he considered an ape on the way to becoming man. It was the skull of a child of about 4 years, and Dart noted that the molar teeth, though large, were humanlike, that the deciduous canine was much smaller than that of an ape, and that the position of the foramen magnum indicated that it would have walked upright. The brain size was however apelike, and other ape features were the projecting muzzle, flat nose, and facial premaxillary suture (Fig. 1).

Dart (1925) named the fossil *Australopithecus africanus* or southern ape of Africa. Many of his colleagues were skeptical of his claims that it was a human ancestor, but the Scots doctor and paleontologist Robert Broom supported Dart's interpretation and determined to prove it with an adult

Australopithecines, Fig. 1 The Taung child, type specimen of *Australopithecus africanus*

Australopithecines, Fig. 2 Lower face of Sts 52, a male *Australopithecus africanus*

skull. This he did in 1936 when he recovered a crushed adult cranium with good brain cast that had been blasted out during limestone quarrying at the Sterkfontein Caves, South Africa. Broom at first named it *Australopithecus transvaalensis*, but after discovery of a child mandibular symphysis 2 years later, he created a new genus *Plesianthropus* for the Sterkfontein fossils (Broom and Schepers 1946). Broom, later aided by his young zoologist assistant John Robinson, recovered many Australopithecine fossils (Fig. 2) from the Sterkfontein Caves including, in 1947, part of a skeleton with a pelvis that proved conclusively that they walked upright (Broom et al. 1950). They also in 1947 blasted out a well-preserved cranium, Sts 5, that Broom said was a female *Plesianthropus*, and thus the local *Star* newspaper named it Mrs. Ples. The cranium had no teeth preserved but was given a cranial capacity of 475 cc. Later, it was considered that these fossils belong to the same species as the Taung child, i.e., *Australopithecus africanus*, and the name *Plesianthropus* was abandoned.

From 1966 onward, Phillip Tobias and Alun Hughes and later Ron Clarke conducted systematic excavations at the caves and added considerably to the inventory of fossils. Most publications in recent years have considered there to be only one species, *Australopithecus africanus*, in South Africa, but Clarke (2013) has demonstrated that many of the fossils belong to a second larger-toothed, bulbous-cusped, flat-faced species. Clarke found this second species to be the same as some Australopithecine fossils that Dart's team of the Kitching brothers and Alun Hughes had found at the Makapansgat Limeworks Cave beginning in 1947. Dart (1948) named this species *Australopithecus prometheus* (Fig. 3). These date to around 3 million years ago and are contemporary with *Australopithecus africanus* at both Makapansgat and Sterkfontein. At this latter site, they are found in a deposit (Member 4 of the Sterkfontein Formation) dating to between 2.4 and 3 Ma. Males and females of each species can be determined. For example, within *Australopithecus africanus*, StW 53 is a male (although often wrongly assigned to *H. habilis* – see Clarke 2013), and Sts 5 is a female. Within *Australopithecus prometheus*, StW 252 (Fig. 4) is a male, and Sts 71 is a female (Clarke 2013). In 1998, Clarke (1998) announced a near-complete skeleton of an earlier *A. prometheus* discovered by himself, Stephen Motsumi, and Nkwane Molefe in Member 2 in the Silberberg Grotto of the Sterkfontein Caves (see Fig. 5; Clarke 2019; Clarke and Kuman in press). It dates to 3.67 Ma (Granger et al. 2015). The complete leg and arm lengths of this individual prove for the first time

that at least in this one species *Australopithecus* had legs much longer than arms.

A third South African species was named *Australopithecus sediba* (Berger et al. 2010). It was discovered in 2008 by Matthew and Lee Berger in a cave deposit at Malapa, about 13 km north of Sterkfontein. It has been described on two partial skeletons, a juvenile male with much of its cranium and mandible and an adult female, and dates to ca. 1.9 Ma. It has similarities to *A. africanus*, rather than to *A. prometheus*.

The first discovery in East Africa of what eventually proved to be an early species of Australopithecine occurred in 1939 when L. Kohl-Larsen found a maxillary fragment at Garusi (now Laetoli) near Olduvai, Tanzania. The deposits in which it was found are now known to date to about 3.6 Ma. Survey work done by Mary Leakey and her team in the 1970s (Leakey et al. 1976) uncovered many more such fossils, including a mandible (Laetoli hominid 4, Fig. 6) which became the type specimen of a new species *Australopithecus afarensis* (Johanson et al. 1978). They grouped the Laetoli *Australopithecus* with similar fossils they had discovered at Hadar in the Afar region of Ethiopia. These fossils included the partial skeleton, known as Lucy, and they possessed features, in particular the lower third premolar, which are more apelike than those of the South African *Australopithecus*. Some other very significant fossils of this species are the reconstructed male skull AL 444–2 (Kimbel et al. 2004), an infant skeleton with a skull (Alemseged et al. 2006), a partial skeleton without skull from Woranso-Mille, Ethiopia (Haile-Selassie and Su 2016), and the trail of Laetoli footprints.

This trail (Fig. 7), representing two individuals walking side by side, was discovered by Paul Abell in 1978. He noticed what appeared to be a humanlike heel impression in an outcrop of volcanic tuff. Subsequent excavation revealed a 41-m-long trail made by one large and one small individual. Although the footprints are those of a bipedal walker, they demonstrate some apelike features, including a slightly divergent big toe and a medial expansion of the abductor muscle of the big toe. Such features are consistent with the foot anatomy of the *A. prometheus* StW 573 skeleton from Sterkfontein. That fossil also has a slightly divergent and mobile big toe that would have been useful for tree climbing.

A canine tooth found at Laetoli in 1935 was so large that Louis Leakey thought it was a monkey. It was only in 1981, with the hindsight of many similar discoveries of large canines, that Tim White recognized this canine in the British

Australopithecines, Fig. 6 Laetoli Hominid 4, the type mandible of *Australopithecus afarensis*

Australopithecines, Fig. 7 Laetoli footprints of *Australopithecus afarensis*

Museum as that of an *Australopithecus afarensis* discovered 1 year before Broom's first adult *Australopithecus* from Sterkfontein. An anterior portion of mandible with all its premolars and canines and one incisor from Koro Toro in Chad, dating to about 3.5 Ma, has similarities to *Australopithecus afarensis* but was named as a new species, *Australopithecus bahrelghazali*, by Brunet (1996).

Jaws of an even earlier and more primitive species of *Australopithecus*, dating to 4.2 Ma ago, were discovered by Meave Leakey's team at Kanapoi in Kenya and named *Australopithecus anamensis* (Leakey et al. 1995). This followed the recovery from that area of a hominid distal humerus by Bryan Patterson's Harvard expedition

in 1965. Two years later, Patterson's team recovered part of a hominid right mandibular ramus with a heavily worn first molar at the site of Lothagam near the shore of Lake Turkana, Kenya. This fossil site, rich in Miocene fauna, had been found by Larry Robbins, at that time a University of California, Berkeley, student, and it is possible that the hominid mandible is a representative of *Australopithecus anamensis*. It was generally thought that *A. anamensis* was directly ancestral to *A. afarensis*. However, the discovery of a 3.8 Ma old cranium of *A. anamensis* from Woranso-Mille, Ethiopia prompted Haile-Selassie et al. (2019) to question that scenario, especially as the two species overlapped in time by at least 100,000 years.

In August 1999, Justice Erus, a member of Meave Leakey's field team, discovered at the site of Lomekwi west of Lake Turkana in Kenya, a cranium dating to about 3.3–3.5 Ma. Although like *A. afarensis* it had a small brain and relatively small teeth, it differed in having a broad, flat face. Hence it was given the name *Kenyanthropus platyops* (Leakey et al. 2001). In this respect, it has similarities to the much later *Homo habilis* cranium, KNM-ER 1470, and could possibly be ancestral to that species. Also from ca. 3.3 to 3.5 Ma at Woranso-Mille in Ethiopia were found a maxilla and two mandibles that differ from both *K. platyops* and *A. afarensis*, and thus they were placed in a new species *Australopithecus deyiremeda* (Haile-Selassie et al. 2015). Thus as these authors observe, there are indications of multiple hominid species in East Africa overlapping in the same areas at the same time.

Another *Australopithecus* species dating to 2.5 Ma was recovered from Bouri, Middle Awash, Ethiopia, and named as *Australopithecus garhi* by Asfaw et al. (1999). A partial cranium has very large cheek teeth, combined with a large, prognathic anterior dentition. A partial arm (incomplete humerus, radius, and ulna) and femur shaft are also attributed to this species.

From much younger deposits in Olduvai Gorge, Tanzania, and from East Lake Turkana, there are some hominid fossils that have generally been accepted as representing *Homo habilis* but which have close resemblances, including small brain size, to the South African *Australopithecus africanus*. These fossils dating to under 2 Ma are OH 24, OH 62, OH 13, and KNM-ER 1813. They occur in the same areas and same age deposits as much larger-brained fossils of *Homo habilis*. Thus, they seem to represent late-surviving *Australopithecus africanus* or a closely related form.

Although the earliest stone tools date back to 3.3 Ma at Lomekwi in Kenya and from 2.6 Ma in Ethiopia at Gona and Ledi-Geraru (see "▶ Oldowan Industrial Complex"), none has ever been found with *A. anamensis*, *A. afarensis*, *A. africanus*, or *A. prometheus*. At later sites, it seems more probable that early *Homo* was responsible for the tools. In the 1950s, Raymond Dart published many articles, as well as a book, claiming that *Australopithecus* had a bone tool culture that he named the osteodontokeratic. Subsequent investigations have shown that there is no justification for such claims and that the accumulations of damaged skulls and broken bones were the natural result of carnivore predation, porcupine collecting, and rock fall and pressure within the cave deposits. The complete hand of *A. prometheus* at 3.67 Ma from Sterkfontein shows that very early hominids possessed a hand physically capable of making stone tools. At least by 3.3 Ma, stone tools were being made at Lomekwi in Kenya, possibly by *K. platyops* (see "▶ Oldowan Industrial Complex").

Another form of Australopithecine in addition to *Australopithecus* is the flat-faced, large-toothed ape-man called *Paranthropus*. This was first discovered by a schoolboy, Gert Terblanche, at Kromdraai, near Sterkfontein, South Africa, in 1938, and named *Paranthropus robustus* by Robert Broom. Details on this form of ape-man are given under the entry *Paranthropus* in this encyclopedia.

The several species of Australopithecine are represented over a large part of Africa, and although there have in the past been suggestions that isolated teeth and jaw fragments from China and Java are Australopithecine, there has been no indisputable support for this. It seems probable that the fossils in question are those of *Homo habilis* that had spread from Africa to Asia.

Paleoenvironmental information suggests that many of the Australopithecines were associated with woodland or tropical forest close to lakes and rivers. Their diet, as suggested by their dentition, varied from omnivorous to more vegetarian for *Paranthropus*. All Australopithecines were bipedal with humanlike hand proportions, humanlike (but large) cheek teeth, and small brain size ranging from about 430 ccs in some *Australopithecus* to 530 ccs in some *Paranthropus*.

These apelike brain sizes, and many other apelike features in the skull and skeleton, coupled with the humanlike bipedality, hands, and teeth, mark them as transitional between Miocene ape and Pleistocene human. There is, however, no clarity on which, if any, of the several known Australopithecine species (except perhaps for *K. platyops*) was ancestral to *Homo*, which was a contemporary of both *Paranthropus* and late forms of *Australopithecus*, e.g., at Olduvai Gorge Bed I.

Authentication and Conservation in Archaeological Science

Nancy Odegaard[1] and Vicki Cassman[2]

Introduction

Authenticity is one of the most influential factors for determining the course of action of heritage in need of conservation. Determining exactly what constitutes a site or objects' authentic state can be problematic and challenging because there is not one history rather a series of histories and stakeholders to consider. Authenticity in conservation is guided by the ethics behind how a place or object should be perceived and protected.

Since the late seventeenth to early nineteenth century, when archaeology as a science developed in the "age of enlightenment," authenticity has referred to the material condition of something original and unique. For this period of Western cultural history, authenticity denoted a relation to genuine identity. The physicality (tangibility) of archaeology and the concept of successive strata served primarily for dating and proof process of authenticity. Archaeological objects unearthed within specific layers became recovered symbols of that historical occupancy. Collectors were known to refer to archaeological objects as ranging from genuine antiquities to imitations of high artistic merit and forgeries of little value. Early conservation treatments sought to retrieve the past through restoration or to bring an artifact back to an original condition. The degree of discernable restoration treatment could move an artifact up or down within this authenticity scale based on visual determinations and skill of the observer.

In the second half of the twentieth century, new technologies enabled tests (laboratory results) for determining authenticity through provenance and dating to accompany the previous role of strata or archaeological typology (documentation). Technical studies replaced the role of assessing aged decay and patina for assigning authenticity. Within Western conservation by the end of the twentieth century, interventions meant to "improve" were considered inauthentic.

Today, at its simplest, authenticity refers to the presence of original material. But authenticity is much more. A practical approach for assessing physical authenticity in conservation treatments may include four authenticities: materials, workmanship, design, and setting. Jokilehto (1993: 59–75) elaborates that treatment must maintain authenticity by maximizing retention of historical material and ensuring harmony with original design and workmanship and not allowing new additions to dominate over the original fabric but respecting the archaeological potential.

If authenticity is the ability to convey significance, then in archaeology, it is also context dependent because sites and their objects can have different meanings at different times, in different places and to different people. Lowenthal (1999) clarifies that this should include origin and

evolution and the recognition of multiple histories and stakeholders.

In addition, social value authenticity helps to clarify aspects of (value) spirituality or possibly sentimentality. Economic authenticity helps to clarify sustainability and development (tourism, trade, insurance, or market value).

Beyond these refinements, one sometimes hears reference to *an aura of authenticity* about a place or object. However, there are many examples that illustrate that rather than being an attribute, both aura and authenticity can be created. This conundrum is what makes the discussion of authenticity and conservation an interesting challenge for all concerned with the preservation and protection of sites, monuments, and objects of cultural heritage.

Definition

Cultural sites and objects are particularly vulnerable to deterioration due to their past utilitarian roles, postexcavation lack of maintenance, and continuous exposure to agents of decay. Unfortunately, warning signs that conservation is needed become visible after deterioration has already taken place. Some terms of condition that reflect a loss of accuracy include:

- Dilapidation or structural deterioration: a state of disrepair or nonfunction by misuse, neglect, or abandonment often resulting in loss of validity
- Dismemberment or fragmentation: a state of being divided, cut, torn, broken into parts, and resulting in loss of integrity
- Disfigurement or surface insecurity: a state of instability or vandalism, potentially resulting in loss of legitimacy
- Recreation or use of replacement parts: non-original components added to augment the structure using nonindigenous technologies and materials, potentially leading to loss of accuracy
- Disenfranchisement: heritage that is deprived of the traditions of community use and loss of accuracy or relevance

In practice, authenticity has a significant effect on our choices of conservation interventions (Jerome 2008: 4). Unfortunately, the word conservation has slightly different meanings for professionals working in the environment of built immovable heritage (sites, monuments, and structures) and professionals working with moveable object collections (in museums). Conventional uses of the terms related to conservation are included in Table 1.

The comparison of basic definitions of conservation, preservation, and restoration for immovable and movable heritage shows that the fields are not in sync. For heritage professionals dealing with sites and buildings, conservation is the umbrella term for the overall goal of the profession, while object conservators use the term preservation for this purpose. It is useful to note that in the United States, conservation does not typically apply to buildings, but to other cultural objects. Preservation for buildings and sites refers to the steps taken to achieve overall conservation, while objects conservators refer to the conservation methods needed to achieve overall preservation of artifacts, hence in the USA the difference in titles: preservationists (sites and buildings) and conservators (objects).

Though the working definitions for conservation and preservation differ between the fields, both definitions fall under the relatively new term heritage science which involves managing change and risk and maximizing social, cultural, and economic benefit not just today but in such a way that we can pass on to future generations that which we have inherited. Scientists carrying out heritage science research range across a number of physical and natural science disciplines and their applications, including archaeological science, building science, engineering and technology, computer science, conservation, environmental science, physics, chemistry, biology, engineering, and environment (House of Lords 2006: 2.21 and 3.17). Olsen (2001: 213) warns that at times heritage scientists assume that knowledge is open and available to all, but in reality it is the powerful nations that are the subjects of knowledge and the rest of the world is rendered as object.

Authentication and Conservation in Archaeological Science, Table 1 Terminology

Immovable (Sites and built environment)	Moveable (Objects)
Conservation: all efforts designed **to understand** cultural heritage monuments, groups of buildings, and sites of cultural value); know its history and meaning; and ensure its material safeguard and, as required, its presentation, restoration, and enhancement (World Heritage Convention. Article I)	*Conservation:* all **measures and actions** aimed at safeguarding tangible cultural heritage while ensuring its accessibility to present and future generations. Conservation embraces preventive conservation, remedial conservation, and restoration. All measures and actions should respect the significance and the physical properties of the cultural heritage item (International Committee on Museums-Conservation Committee)
Preservation: methods of maintaining the historical integrity of a building with limited alterations or additions; methods of stabilizing and preventing further decay (National Trust for Historic Preservation). This term is considered more specific than conservation	*Preservation:* the **protection** of cultural property through activities that minimize chemical and physical deterioration and damage and that prevent loss of informational content (American Institute for Conservation). This term is considered to be broader than conservation
Restoration: methods used in rebuilding buildings and structures with **historically accurate materials** to achieve historical authenticity in keeping with a particular time period or event. There is a focus on maintenance of intact historic features, replacement of lost features, and removal of inappropriate features (US Secretary of the Interior's Standards for the Treatment of Historic Properties, 1995)	*Restoration:* all actions directly applied to a single and stable item aimed at facilitating its appreciation, understanding, and use. These actions are only carried out when the item has lost part of its significance or function through past alteration or deterioration. They are based on respect for the original material. Most often such actions modify the appearance of the item. Examples of this restoration are retouching a painting, reassembling a broken sculpture, reshaping a basket, filling losses on a glass vessel (International Committee on Museums-Conservation Committee). In the United States, it refers more specifically to the treatment procedures intended to return cultural objects to a known or assumed state, often through the **addition of non-original material** (American Institute for Conservation)
Reconstruction: is the process of depicting, by means of **new construction**, the form, features, and detailing of a nonsurviving site, landscape, building, structure, or object for the purpose of replicating its appearance at a specific period of time and in its historic location (US Secretary of the Interior's Standards for the Treatment of Historic Properties)	*Reconstruction:* is less commonly used with objects but may refer to an aspect of the conservation or restoration process where new materials are used to create a replacement part of the structure (i.e., a missing chair leg) or if collapsed parts are reassembled
Rehabilitation: actions that emphasize the **retention and repair** of historic materials on deteriorated property with a focus on those materials, features, finishes, spaces, and spatial relationships that, together, give a property its historic character (US Secretary of the Interior's Standards for the Treatment of Historic Properties)	Term not commonly used
Anastylosis: reconstruction or reassembly of collapsed or fallen parts into their original place and when necessary, incorporating new materials (World Heritage Sites)	Term not commonly used

Historical Background

"Each generation views authenticity in a new guise, reflecting its new needs for truth, new standards of evidence, and new faiths in the uses of heritage" (Lowenthal 1999). A coherent philosophy for conservation began to emerge in the last quarter of the nineteenth century. At this time, manuals for the conservation of ancient buildings were developed, and authenticity was identified as a concern. By the 1920s, Marshall (1923: 10) wrote: "Although there are many ancient buildings whose state of disrepair suggests at first sight a renewal, it should never be forgotten that their *historical value is gone when their authenticity is*

destroyed, and that our first duty is not to renew them but to preserve them."

Philosophies, treaties, various heritage charters, and conventions were organized and laid the foundation for the advancement of doctrine, practice, and dialogue in conservation. Lowenthal (1999) summarizes that the focus has moved from possession of authenticity to an "authenticity of materials and form, of structure and process, and of aim and intent, moving from exclusive concerns with buildings and artifacts to broader considerations of landscape and nature, folklife and folklore, ideas and beliefs."

Highlights from some of the important international gatherings that have defined conservation for archaeological sites and monuments are outlined below.

The Athens Charter for Restoration of Historic Monuments, organized by the International Museums Office in 1931, established basic principles for an international code of practice for conservation. It recognized a common responsibility to safeguard monuments for future generations as our duty to hand them on in the full richness of their authenticity. Reference is made that "the work of consolidation [use of modern materials such as reinforced concrete] should whenever possible be concealed in order that the aspect and character of the restored monument may be preserved" (Article 4) and that "the architects and curators of monuments should collaborate with specialists in the physical, chemical, and natural sciences with a view to determining the methods to be adopted in specific cases" (Article 5.1).

The Venice Charter for the conservation and restoration of monuments and sites, organized by the International Congress of Architects and Technicians of Historic Monuments in 1964, established that "it is our duty to hand them [ancient monuments] on in the full richness of their authenticity" (Preamble) and that "ruins must be maintained and measures necessary for the permanent conservation and protection of architectural features and objects discovered must be taken" (Article 15). This Charter also identified conservation judgments as necessarily relative and contextual as opposed to a belief in international absolutes.

The guidelines developed in Venice in the 1960s became problematic when authenticity in heritage went beyond the stone remains of past structures that have inherent relative permanence. Consideration of rebuilding to preserve traditional techniques and forms of living and changing cultures or those created from more ephemeral (i.e., organic) materials challenge the call for permanent conservation and protection in Article 15.

The Burra Charter was first adopted in 1979 and has been revised several times. In 1999, it became known as Burra: The Australia ICOMOS Charter for Places of Cultural Significance. It established that "places of cultural significance must be conserved for present and future generations" (Preamble). "Cultural significance means aesthetic, historic, scientific, social or spiritual value for past, present or future generations. Cultural significance is embodied in the place itself, its fabric, setting, use, associations, meanings, records, related places and related objects. Places may have a range of values for different individuals or groups" (Article 1).

The Nara Document on Authenticity, organized by the World Heritage Committee in 1994, opened the world to discussions involving the essential role of understanding of authenticity during the scientific study of cultural heritage. It expanded the range of values for authenticity to accommodate the mainstream Japanese conservation practices of dismantling, repair, and reassembly. The broader framework for authenticity analysis developed at Nara inspired regional meetings that were held in Africa, Europe, the Americas, Australia, and China. The Nara Document establishes that "the conservation of authenticity contributes essentially to the clarification and illumination of the collective memory of humanity" (Article 4) and "judgments of values and authenticity must be considered and judged within the cultural contexts to which they belong" (Article 11).

The Declaration of San Antonio, organized by ICOMOS in 1996, suggested expanding proofs of authenticity to include reflection of true value, integrity, context, identity, use, and function. It states that "the authenticity of our cultural resources lies in the identification, evaluation, and interpretation of their true values as perceived

by our ancestors in the past and by ourselves now as an evolving and diverse community" (that coexist but often assign different values to them) (Article 1) and "when an archaeological site is no longer used by the descendants of [its] builders, the material evidence of the site provides the most direct link to the past which makes it possible for the present inhabitants to perceive and interpret the sites meaning and value" (Article 5).

The Zimbabwe Meeting Recommendations in 1999 state: "In the context of the World Heritage Convention, the notions of authenticity and integrity cannot be expressed in isolation.... The meaning of the heritage is usually a combination of values created by people. These values include norms and belief systems, as well as material and technological aspects. In most instances culture and nature are inseparable." Basically, it suggests that language, indigenous knowledge, skills, and technology should participate and be documented in preservation and management of heritage. Munjeri has clarified that "in traditional African societies, it [authenticity] is not based on the cult of physical objects 'the tangible' and certainly not on condition and aesthetic values.... The solution lies in recognizing that indigenous communities are at heart, 'ecosystem people' integrally linked to the ecosystem they inhabit. They are part of the integrity equation" (Munjeri 2001: 18–9). This truly complicates the equation by expanding the boundaries of authenticity into the slippery slopes of landscape and identity.

The World Heritage Operational Guidelines (2005, Article 81) provides insight into authenticity and includes a list of information resources: form and design, materials and substance, use and function, traditions and techniques, location and setting, spirit and feelings, and other internal and external factors such as management systems, language, and other forms of intangible heritage. It addresses the reconstruction of archaeological remains or historic buildings or districts as acceptable only on the basis of complete and detailed documentation and recognizes the role to some extent of conjecture (Article 24).

The conservation of objects is a smaller aspect of archaeology than buildings, sites, and monuments, and there are no doctrines, charters, and declarations to illustrate historical perspective. By the end of the nineteenth century, there was an increasing recognition of the importance of preservation for antiquities and a justification for the creation of conservation handbooks. Most provide explanation for deterioration and treatment processes, and the use of before and after photographic documentation is identified in some. By the mid-twentieth century, handbooks for collectors, archaeologists, and museum curators were developed because appreciation and study mandated that objects be cleaned, restored, and repaired. By the last quarter of the twentieth century, an intensification of laboratory training was recommended for the conservation of objects.

The conservation of moveable historic and artistic objects is guided by various codes of ethics developed by professional conservators in numerous countries. These codes are statements of values, standards, and aims that guide the conservator through a complex range of issues. Beginning in the mid-twentieth century, professional organizations for the conservation of historic and artistic works were formed to break with the tradition of the craftsman-restorer. The codes provided generalized and idealized standards of behavior for the new professionals of the later twentieth century who owe their professional training to formal graduate studies devoted specifically to the field of conservation.

Most codes of ethics continue to focus on physical or tangible cultural heritage. For example, the American Institute for Conservation code requires that "statements about age, origin, or authenticity should be based on the physical evidence derived from an object, rather than on opinions, and should include an explanation that scientific data alone cannot provide definite attributions."

Conservators are governed by a respect for the integrity of the object or its unmarred, unimpaired, or uncorrupted condition. Some codes specifically clarify that integrity may include physical, historic, and aesthetic integrity, while others have added a reference to conceptual integrity. The American Institute for Conservation's code calls for "an informed respect for cultural property, its unique character and significance, and the people or person who created it." An important aspect of the Canadian Association of Conservation code is an emphasis placed on

"full documentation without fraudulent intent... the presence and extent of any restoration or reconstruction must be detectable, though they need not be conspicuous." The historian Cesare Brandi is often credited with introducing modern principles for the conservation of art that led to a rejection of imitative restoration and heightened respect for the traces of time and concepts of authenticity in 1963. This concept respects the original and present contexts in the process of reintegration while making the intervention discernable at close range.

In addition to the unwritten "six foot, six inch" rule, meaning a restoration should be discernable at six inches but not at six feet, there is the principle of reversibility that has been a long-standing focus of the conservation codes of ethics. It refers to the capacity of a treatment to be undone or reversed, at a later date, without resulting in damage or change to the object. This is inclusive of any materials such as adhesives or restorations that may be added. Despite numerous commonalities in theoretical approach and practice, the needs of different materials have led many specialist conservators to develop different attitudes and approaches to treatment. Conservators of moveable objects tend to specialize by divisions based on material composition (ceramics, wood, glass, metal, painting, paper, or stone). Other times, the specialties represent types of objects (paintings, books, textiles, sculpture, or architecture), or they may refer to the academic discipline that objects broadly belong to (archaeological, ethnographic, decorative arts, historical, or fine arts) or to a type of material function (furniture, costume, or musical instruments).

At the end of the twentieth century, contexts of value began to influence the conservation of moveable objects. Important examples of change include (1) the concept of a single standard toward conservation treatment (the highest and most exacting standard of treatment for each work) was determined to be impractical, (2) the role of cultural sensitivity that allows acknowledgment of indigenous feelings and the connectedness of different values and priorities toward conservation became significant, and (3) a caution about the removal of dirt and residues because analysis may identify past uses, signature a provenance, or provide a date or place of origin.

Also, it is important to point out where discussions of authenticity do not appear. For instance, it is not mentioned in the 1990 Federal Regulation 36 CFR 79: Curation of Federally Owned and Administered Archaeological Collections, which was promulgated to provide minimum standards for the long-term management and care of archaeological collections, including associated records and reports. Notably, the regulations consider actions that need to be taken for both new and existing collections. Likewise, the Salzburg Declaration of 2009 on the Conservation and Preservation of Cultural Heritage established a new collaborative platform to more effectively preserve the world's cultural heritage, but it does not specifically discuss authenticity. Perhaps the assumption that modifying an object should be done for the sake of authenticity is problematic because all conditions are equally authentic (Muñoz-Viñas 2005: 91–113).

Key Issues/Current Debates

Conservation, as the overall goal for heritage science, has evolved from how to conserve to why conserve to for whom we should conserve. Archaeological sites, monuments, and objects may hold values that conflict with one another. Authenticity is critical to consider in conservation, but it is relative, and as a term it has different meanings in different contexts.

Conservation has focused on the material qualities of archaeological remains to meet the test of authenticity and to implement treatments that arrest and stabilize the process of decay. What was seen as objective criteria, relating to design, material, and workmanship, was used to establish the authentic character for treatment. This works well when cultural heritage monuments and objects belong to a society that has ceased to exist, because faithfulness to original objects, materials, contexts, and aims become a shared common denominator (Lowenthal 1999).

Considering authenticity to be a condition in relation to context means that the revealing of relevant values is also a basis for treatment. But basing authenticity on judgments of intangible value is subjective. Values are subject to cultural and educational processes that may change over

time. Also over time attempts to conserve cultural contexts and aims become more relative and subject to interpretation and negotiation, especially when multiple stakeholders are involved.

Thus, two of the important issues that have emerged regarding authenticity and conservation involve (1) concerns that over-restoration or reconstruction of the tangible original should not destroy value and integrity as in the Venice Charter and (2) concerns that link to intangible cultural values of heritage, which have been maintained over time, should be a primary consideration for meaning and validity as in the Nara Document.

Conservation can claim to provide authenticity through analysis and technical study, but it can also inadvertently remove material authenticity by cleaning away critical evidence. In fact, scientific analysis in the course of conservation is better at producing evidence than it is at proving authenticity. Examples include dating techniques applied to a composition material or elemental analysis of materials known for being indicative of a particular group (based on a body of reference material) or that the wear patterns on an object surface are human made. Continuous developments in science and changes in conservation treatments can complicate investigations into authenticity for ancient sites, monuments, or finds. For instance, Myrberg (2004) summarizes the role of authenticity in ancient monument preservation and provides a problematic example involving a labyrinth on the Swedish archipelago. He asks: "What is a true monument of the past? Many monuments have been reused over the centuries, rebuilt, added to or copied – processes that continue into the present… should their use or even their construction in the present be considered less meaningful than their use or construction in, say, the eighteenth century or the Neolithic?"

An authentic value of inspiration may also be important to conservation particularly when it is linked to artistic, historic values. Brajer (2009) illustrates a confusing history of many re-restorations for wall paintings in a Danish church beginning in the nineteenth century due, in part, to the use of medieval techniques and materials and innovative tricks to achieve the appearance of original wear and tear. The resulting condition was a hotchpotch of overlapping repairs, reconstructions, and over-paintings, presenting a picture of repeated disintegration and partial recreation. A growing consciousness regarding the meaning behind the previous restoration efforts helped the conservators establish a link between value (the source of meaning) in treated objects and the authenticity manifested in them (integrity of meaning).

As conservators learn to look beyond the context of original materials to cultural dialogues and engagements or dialectics, they are better able to deal with interpretative issues that involve complex arrays of contexts, sets of data, or multiple stakeholders. Conflicts such as treatments that conserve the research interests of archaeology with tourism or public values can be negotiated. For example, when the Lucy hominid remains were selected for a traveling exhibition, research scientists were concerned about object safety and their loss of research access. Despite the fact that public visitors to the National Museum of Ethiopia had for years been inspired by a display of a cast and that they thought was original, organizers for the traveling exhibit were convinced that only the real Lucy fossil would be adequate to generate tourism dollars. Conservation compromises allowed the Lucy remains to travel safely, to be handled only by her keeper, to be available to both researchers and museum visitors, and to bring home financial reward.

International Perspectives

International perspectives on authenticity and conservation focus a great deal on notions of tangible and intangible aspects, global and local expertise, and universal and particular principles. The founding of the International Council of Monuments and Sites (ICOMOS) in 1965 by UNESCO initiated a global network of professionals devoted to heritage conservation. The World Heritage Convention of 1972 pledged to safeguard heritage resources deemed to be of *universal* value to all of humanity. Various philosophies, treaties, heritage charters, and conventions have laid the foundation for conservation practice and dialogue. "Imbalances between [in] different regions and types of heritage have led to different approaches to conservation, fueling tensions and undermining exchanges of

ideas and experiences" (Luxen 2004). Today, the relevance of these documents, which have moral rather than legal authority, is sometimes contested, but they serve to remind and challenge us.

Throughout the world, heritage conservation with value based on original fabric is very different from heritage with living or great spiritual value. Dialogue between professionals from different cultures around the world continues to improve the understanding and practice of conservation. Various international meetings in Africa have identified the importance of culture and nature, while in the Far East, the importance of traditional crafts skills as cultural heritage conservation has been acknowledged with the concept of "living cultural treasure." In the Americas, a common indigenous concept of authenticity suggests that "any object or structure reproduced, replicated, repaired, stabilized or restored by descendants of the original craft persons or members of the same ethnic party loses no integrity" (Ladd 1999: 22). In other words, "a structure can be authentic if it closely resembles an ancient structure in form and design or if its spirit and feeling is that of an ancient building" (Holtorf and Schadla-Hall 1999: 235).

Conservators working with archaeological objects in museum collections often find decisions regarding appropriate conservation treatment to be difficult. If values can be aesthetic, historic, scientific, social, or spiritual and may reflect past, present, or future generations, then objects of similar type including ancient originals, historic or honest copies, recent replicas, forgeries, or deceptive replicas created with some original parts married from different objects may all be authentic. Examination and analysis can detect materials of construction; methods of technological production; natural corrosion, residue, salt, or other accretion products versus chemical finishing, false patina, or modern adhesive and paint products; and typical wear marks versus machine tool marks. Based on conservation studies, objects may retain a value but have their authenticity, and cultural significance reassigned. Just as a fragmentary object condition may be an argument for authenticity, replicas can be born out of demand for continuing tradition (sometimes referred to as heritage craft), a lack of the original, or the need to fulfill market demand. Additionally, restoration techniques that include repainting may come to represent an important history for a piece. The concept of authenticity continues to be a fundamental value in the decision making in the conservation and interpretation of archaeology, new approaches towards the display and use of collections are challenging conventions, making the roles of curators, conservators, and archaeologists increasingly complex (Gordon et al. 2014).

Conservation is still challenged in how to include and evaluate the role of authenticity in treatment decision making, how to reconcile the difference between scientific conservation and the revival of heritage craft, and how to allocate time and funding for the conservation of spectacular monuments and objects at the expense of less spectacular ones. Several authors (Layton et al. 2001; Muñoz-Viñas 2005; Stanley-Price and King 2009) have offered thoughtful discussion on these subjects. Justifications for reconstruction (returning a place to a known earlier state by the introduction of new material into the fabric) would rarely meet the requirements of the Charters that they are based on but can and do satisfy a variety of vital stakeholders nonetheless.

Future Directions

Local knowledge and public participation have become recognized components in site preservation efforts. Avrami (2009) explains that social theorists offered their application to planning, which resulted in "broader participation of stakeholders, challenged top-down expert-driven models, and helped to transform planning into a more social and contextually-responsive endeavor."

The stewardship of sites and monuments is very tied to subjective relationships between people and places. The repainting treatment project of the Kamehameha statue in Hawaii is an example of how a conservation project could be directed with community-centered goals. The first goal included standard conservation procedures, except they were based on the community's decision about whether to paint or gild the statue and how to train local community members to effectively maintain the sculpture into the future. The

second goal was to establish a link to future regional development with traditional arts, heritage preservation, and community identity. The use of participatory conservation offers a model for bringing this knowledge into play-making the conservation process a vehicle for public engagement and as a tool for critical discourse about how conservation represents the past (Wharton 2002). Measures of monitoring treatment relevance, improving management frameworks, and humanizing documentation may also benefit from the inclusion of various stakeholders.

Finally, repatriation rights for sites and objects for indigenous groups are but one example of how decisions of conservation can vary for different people at different times. A critical aspect of the repatriation process in the United States is the role of consultations in determining control, treatment, and disposition of human remains and sacred objects and is outlined in 43 CFR 10.5, 10.8 (a), and 10.9 (b). The repatriation process can be subjective and political, and it can actually be an appropriate reverse of conservation when objects and human remains excavated from a burial are reinterred together, or when sacred objects are left to naturally deteriorate as intended.

Sullivan (1998: 8) aptly identifies two important issues that are relevant for all future discussions: "(1) that over-restoration or reconstructions not destroy the value for which the site is listed as a World Heritage Site and (2) that the idea of authenticity is indissolubly linked to cultural value and only has meaning and validity in this context. Thus an appropriate treatment to conserve authenticity will vary depending on the primary cultural values of the place."

Authenticity in conservation has come to require a sense of respect for the place, the indigenous people, and the local history and implies a means of linking to the future as part of a flow of time. Stressing an understanding of knowledge rather than collecting, testing, and presenting facts is important for the integrative stewardship of sites or the preventive conservation and management of collections. National symbolism, continuing function or reuse, education and research, tourism promotion, and site preservation are all linked to sustainability of cultural heritage. Debate over how best to conserve material culture will continue. Some will argue for minimal intervention, while others will argue for extensive restoration and active use of cultural heritage. The recognition of cultural relativism and contested meanings embedded in material objects has formally entered conservation literature (Odegaard 1995; Clavir 2002).

Authenticity and Pastness in Cultural Heritage Management

Cornelius Holtorf
School of Cultural Sciences, Linnaeus University, Kalmar, Sweden

Brief Definition of the Topic

Authenticity is about what you can trust to be what it purports to be, and cultural heritage is about what evokes the past in a given social context. Consequently, authentic cultural heritage is about what you can trust and evokes the past in society. This quality is often assessed by various ways of determining the age of the heritage in question. But dating does not sufficiently take into account the perceptions of the audience. For something to evoke the past in a given social context, it does not have to be old. Instead of focusing on age, we must therefore focus on the perceived quality of being of the past, as it is the presence or absence of this perception that determines whether or not something is trusted to evoke the past in society.

The Austrian art historian Alois Riegl's (1857–1905) argued in a classic essay on "The Modern Cult of Monuments" that the visual perception of traces, such as corrosion, patina, and general wear and tear, "testify to the fact that a monument was not created recently but at some point in the past" and thus confer age value on the

monument (Riegl 1982 [1903]: 32). What becomes apparent in age value is not, however, the historical origin of a given object but its pastness. Pastness denotes the perceived quality of something to be of the past (Holtorf 2013, 2017). The presence or absence of pastness is not related to an object's physical properties and age but the result of a particular perception and, as such, firmly situated in a given social and cultural context (see also Dawdy 2016). A ruin may possess pastness because its walls are in an obvious state of decay, irrespective of when it was built. Similarly, an object on display in a glass case as part of a historical exhibition may be considered of the past because a label or guide is saying so. If we want to understand and manage cultural heritage with regard to all the important roles it fulfills in contemporary societies, an important question for future research is under which conditions human audiences perceive such pastness and whether or not the concept has global validity.

Holtorf (2017) argued that there are three specific criteria of which at least one, but better several, needs to be fulfilled for pastness to be present:

- Pastness requires physical clues: an object acquires age value through material traces of wear and tear, decay, and disintegration.
- Pastness requires correspondence with expectations: audiences need to recognize objects of the past as such.
- Pastness requires a narrative: a plausible and meaningful story has to link past origin and contemporary presence of a given object.

Instead of asking whether a given object originated in the past and, if so, when, we should henceforth pose the question whether it possesses pastness, in other words whether it is trusted by relevant audiences to evoke the past in society. Established distinctions between authentic and fake, original and copy, past and present, old and new, and other and same are not helpful for understanding the character and function of heritage in the contemporary world and, therefore, need to be overcome. Recognizing the significance of pastness means that there is a need for heritage studies and the professional heritage sector to concern themselves with a much wider range of objects and phenomena in society than has conventionally been the case.

Authenticity and the Manufacture of Heritage

Nezar AlSayyad[1] and Sylvia Nam[2]

[1]College of Environmental Design, University of California, Berkeley, CA, USA

[2]Department of Anthropology, University of California, Irvine, CA, USA

Introduction

The desire for authenticity pervades all facets of modern life. Authenticity, accordingly, constitutes an important site on which tradition and modernity have been debated and reformulated. The recovery of tradition – the cataloguing of the

past through material, social, and cultural forms – has allowed narratives of modernity as a future-oriented enterprise imaginable. As illuminated in writings on the interlocking pair of tradition and modernity (e.g., Mitchell 1991; Wright 1991), tradition came into being only when it was imagined as a defining complement of modernity not only temporally – with tradition linked to the past and modernity with the future – but also spatially through the built environment (see Roy 2004).

If authenticity is an important discursive site of tradition and modernity, the built environment serves as an actual terrain on which the recovery of tradition, on one hand, and the elaboration of modernity, on the other, have been displayed. Nowhere is the recovery of tradition more apparent than in defining the meaning of heritage. Like tradition, heritage implies continuity not only with the past but with a past determined to be historically suitable. Yet as Eric Hobsbawm and Terence Ranger (1983) 1) have stressed, "traditions" that "appear or claim to be old are often quite recent in origin and sometimes invented" as is captured in their concept, "invented traditions." The notion of invented traditions suggests that the distinction between tradition and modernity is itself constructed and that authenticity as a proxy for originality or as a marker of differentiation must be questioned.

Extending the concept of invented traditions to the built environment, this entry examines how heritage sites that may appear authentic are oftentimes manufactured in the service of the tourism economy. Specifically, it looks at how heritage itself has become a commodity that is valued through circuits of travel and consumption. Tradition and heritage, recovered and restored as well as invented and manufactured, have been central to the making of the nation-state and in constructing nostalgia-based notions of identity. From an economic standpoint, heritage sites have become invaluable sources for communities, cities, and nations through which to cultivate symbolic capital and accumulate profits. As heritage sites become increasingly commodified and commercialized under late capitalism, the authenticity of heritage has become a taken-for-granted concept whose meanings are assumed but not specified.

The built environment, or "space" broadly conceived, has been identified as part of the web of social experience crucial to forging cultural consciousness (Harvey 1990). When viewed at the intersection of tradition and built form, the built environment has been understood as a "system of settings" or a "cultural landscape" (Rapoport 1989). These conceptualizations highlight the built environment's crucial role as a mediator of values, symbols, power relations, and culture. Rooted in the interdisciplinary perspectives of architectural history and urban studies, this entry focuses on the meaning of authenticity and the manufacturing of heritage evident in the proliferation of placemaking practices and the revalidation of locality as it relates to two shifts. The first shift is economic with tourism, a central vehicle for the acquisition of culture and the experience of authenticity. Tourism generates economic and symbolic values for localities vying for positions in a global order of places. Capitalism, with its infinite ability to commodify everything, has engendered new regimes of production and consumption where commodities are no longer manufactured goods but cultural landscapes, among them heritage environments. The second shift is discursive. Tourism both advances and depends on the trope of authenticity. As evidenced in former colonial cities that are refashioned for global tourism, for example, the marketing of such sites draws upon and extends older myths on the authenticity of "the Orient" or "Africa." The production of these landscapes, cultural commodities under contemporary capitalism, has transformed space and history and made them spectacular. Heritage, by extension, can be understood as a spectacle on display where the phantasmagoria of authenticity is also the source of its profitability (AlSayyad 2001).

Definition and Historical Background

Genealogies of a Concept

Built environments unite capitalism and culture as exemplified in landscapes that are packaged for consumption in the global economy of tourism. In such regimes of tourism, heritage is manufactured

for consumption. Manufactured heritage has become a new norm in tourism development with entire built environments constructed to cater to and order difference. Paradoxically, the advance of mass tourism has led to the dismantling of actually existing traditional places and historic sites. Because the built environment is both spatial and visual, the trope of authenticity has been central to a system of classification and representation of place in these cultural landscapes. Authenticity conditions knowledge of a place and underwrites the values that are brought to bear upon this knowledge. That heritage is manufactured is to suggest that heritage, culture, and tradition are part of the modes of production not of the industrial economy, but of the cultural economy. Rather than goods that are produced to be consumed, heritage along with the signs and representations of culture is manufactured for consumption. Heritage as a commodity aligns with its root definition as property that is owned.

The purpose of this evaluation of the manufacture of heritage is not to expose an assumed artificiality or constructedness of heritage per se. Rather, the proliferation of manufactured heritage necessitates a look at how heritage is fashioned. Part of this fashioning is the language of authenticity, whether for its symbolic power or in the ways authenticity as an idea imparts value to the traveling experience. Etymologically, authenticity is from the Greek word *authentikos* or genuine. It denotes a state of being in accordance with fact or reality, truth in substance, or in origins and authorship. In social life, however, authenticity functions as a keyword. According to Nancy Fraser and Linda Gordon (1994), following Raymond Williams (1976), keywords used to describe social life are "active forces in shaping it." By underscoring the constitutive dimension of language, Williams shows how keywords are sites through which social experience is mediated and defined. Earlier, Theodor Adorno (2003 [1964]) cautioned against the allure of semantic games that compromise the task of critical thought. The "fact that the words of the jargon sound as if they said something higher than what they mean. . .the terms of the jargon of authenticity are. . .words that are sacred without sacred content" (Adorno 2003 [1964]: 6). Directed at existentialist philosophers who relied on authenticity as a key trope to critique society's values, Adorno stressed the ideology of language in what he called the "jargon of authenticity." For Adorno, jargon was like an "aura." Following Walter Benjamin, an aura refers to a "strange weave of space and time: the unique appearance or semblance of distance, no matter how close it may be" (Benjamin 2005 [1931]: 518) and provides a means to understand the possibilities of authenticity yielded by new cultural forms.

In the study of the built environment, authenticity is both constitutive in the sense elaborated by Williams and ideological in the way stressed by Adorno. As a keyword, authenticity has held a dialectical hold over the field of heritage studies in its ability to shape the discourse as well as name one of its key premises. As a jargon, authenticity is used extensively in heritage debates, though with limited analytical utility. Authenticity is often treated as a state of being or as a fundamental characteristic inhered in the built environment. Authenticity ascribes value to heritage or those buildings, landscapes, and monuments historically validated and contextually valued through their transmission across generations. Conversely, built heritage is assumed to be authentic as a space that instantiates history or heritage that displays the past from the position of the present. Indeed, authenticity occupies a paradoxical position in that odd coupling, "authentic heritage." The yoking of these two terms – authenticity and heritage – renders "authentic" an empty signifier or exposes its redundancy specifically when the term "heritage" is unpacked.

Heritage, which derives from the Old French meaning to inherit, denotes property that is valued and transmitted across generations. This ascription of value is crucial. Heritage, whether in the form of objects, traditions, or material culture, acquires its value from a history established through documentary evidence as well as through a set of authorized narratives. For travelers, the authenticity of tourism imparts "distinction" in the sense outlined by Pierre Bourdieu (1984) to those who "consume" heritage sites, exotic locales, and faraway destinations. Bourdieu's focus on the

political dimension of consumption suggests that tourism is one of many strategies used by social groups to maintain and reproduce class power and privilege.

The "interpretative turn" (Rabinow and Sullivan 1987 [1979]) in the social sciences was an epistemological as well as methodological shift away from positive science to a hermeneutic approach in the analysis of human practices, discursive strategies, and systems of knowledge. Decades later in 2003, a similar turn took place when UNESCO (the United Nations Educational, Scientific and Cultural Organization) set out to include "intangible heritage" in its definition of cultural heritage. UNESCO has long ignored the political dimension of culture appealing to culture's universality. In expanding the meaning of heritage, the UN agency expanded its original mandate as a steward of culture. Following its reclassification, intangible heritages – those immaterial practices such as oral traditions and performing arts – were deemed to have equal claim to heritage status as much as tangible heritage or buildings, monuments, and objects that have long served as the core of heritage.

The distinction between intangible and tangible heritage relies in part on the trope of authenticity as well as the difference of materiality. But what is equally at play in this expanding category of heritage is the nexus of power and knowledge – experts in planning, preservation, and architecture as well as in history and anthropology who are able to recover places, norms, and customs and categorize them. Such categorization suggests that authenticity is not an essence or a thing, but rather contextually driven if not malleable. Places and objects are not inherently authentic. Rather, heritage and authenticity are interpretative categories with certain icons of visibility – the monument or the landscape – that are part of multiple systems of significance, practice, and meaning.

Before going into greater discussion of the manufacture of heritage, it is important to situate the emergence of heritage as part of an emergent cultural consciousness. This desire for knowledge and culture was institutionalized through specific mediums that are central to heritage preservation today – mediums based on specific formalized apparatuses of intelligibility. Among these institutions of intelligibility, codified through colonialism, have been the museum and the world exhibition. These two institutions reflect a nexus of power and knowledge over place that in turn legitimated the colonial enterprise. The museum was part of the classificatory system of the colonial state that functioned as a "pictorial census" (Anderson 1991 [1983]) or a means of governing through categories of identity that allowed for culture to be fixed to a delimited locale or territory. The world exhibition was another institution through which culture – through its visibility – was given object status. These apparatuses continue to be relevant today.

Key Issues

From Colonialism to Global Capitalism

As outlined in AlSayyad (2001), heritage can be contextualized within three historical moments. The first corresponds to late colonialism during which interest in indigenous heritage became initially catalogued and classified. The second period followed decolonization in the period of post-colonial nationalism during which newly emerging nation-states used heritage and authenticity as markers, paradoxically enough, to assert a modern identity. The last is this era of twenty-first-century global capitalism where heritage production has become a new frontier of accumulation, placemaking, and positioning. The periodization below serves to illuminate relevant debates rather than to indicate strict historical brackets. In what follows, this entry examines the intersection of authenticity and heritage through the lens of the built environment. The manufacture of heritage can be considered the aesthetic organization of space-history under the demands of modernity. All heritage is manufactured in the way that all traditions are invented. Heritage must also be seen as the articulation and management of difference and as a preoccupation with defining a position and place in a globalizing world. The concern here is with the ways in which historical knowledge is not only mediated through something called heritage but how it is mediated through space, that is,

in built form. This requires moving away from a normative reading of heritage as a set of truths and essences but rather as social constructions and systems of representation that make claims to truth, to identity, and to history.

Authenticity as Recovery: The Colonial Ordering of the World

Modernity has been a central platform of engagement with the meanings, discourses, and representations of heritage and tradition. In his treatise on experiences of modernity, Marshall Berman (1988) juxtaposes the inauthentic modernity of St. Petersburg, what he calls the "modernism of underdevelopment" with the authentic modernity of Paris associated with progress, reason, and the future. While modernities of the Global South have been riddled with questions surrounding the authenticity of the copy or modernity as mimicry, traditions are assumed to be locatable in and native to the Third World. Authenticity and tradition have been treated as stable and positive configurations, associated with the weight of the past deemed to contrast to the dynamism and change of modernity. Yet as noted below, heritage and tradition were representations of culture and power that were erected into reality.

The first systematically visual display of heritage emerged through the world exhibition and the museum. Museums and exhibitions became the staging grounds on which colonial heritage could be rationalized and represented for the consumption of metropolitan viewers. In the colonial order of things, tradition and modernity could be mapped according to the separation of the world between the West and the non-West or in more recent parlance between the Global North and Global South. Authenticity was reconstituted under colonial rule as the grounds from which to recover tradition and heritage. Thus, tradition was located in non-Western societies and modernity in the West. However, the colonies were also important sites to experiment with modernity and to work through what would become policies of public health, education, sanitation, and urban planning. The colonial encounter was thus crucial in sustaining if not consolidating structural dualisms that have framed much of Western social thought – modernity versus tradition, use-value versus exchange value, and core versus periphery. The museum along with the exhibition transformed objects into historical evidence and valorized landscapes as heritage. The colonial imagination, through such instruments as the exhibition and the museum, was made into reality as colonial administrators and scholars categorized heritage environments and displayed them for public consumption.

Scholars of postcolonial theory and cultural studies have pointed to the multiple temporalities and reconstructions of history associated with the emergence of colonial nostalgia as a cultural phenomenon, as a nostalgia that positions the past as critique of present, or as a cultural practice connected to revisionist history and politics. Edward Said (1978) has identified this process as the "citationary structure" of Orientalism where the repetition and the circulation of the same notions become sedimented and legitimized as assertions of authenticity and truth.

An example of authenticity as recovery can be found in the Cairo Street or Rue de Caire that was built as part of the Paris Exposition of 1889. As detailed by Zeynep Çelik (1992), Cairo Street was willingly financed and authored by Delort de Gleon, a wealthy Frenchman who had lived in Egypt for a quarter of a century. His concern for authenticity was so deep that he imported dirt and donkeys directly from Egypt as well as actually existing historic structures including a Quranic school and a water fountain that were disassembled, shipped to Paris, and finally installed at the exposition site. Gleon argued that the Rue de Caire was in fact more authentic than the streets of Cairo based on the reasoning that it was impossible to find an untouched, and thus authentic, street in Cairo.

Authenticity and Postcolonial Nationalism

Benedict Anderson (1991 [1983]) argues that nationalism was made possible and new communities imaginable through the interplay between technology and the relations of capitalist production. In order for a nation to be modern, it had to produce a past. Time, made continuous and linear, became central to the construction of an

appropriate history and identity that would be coextensive with territory of the imagined community of the nation. Chronological time, measured by the clock and calendar, coupled with the technologies of capitalism made it possible to represent the nation. Such forms of representation – whether print commodities like the newspaper – made new communities imaginable.

Landscapes were brought into the horizons of intelligibility and knowledge through other forms of representation as well, among them the map and the census, allowing the contours of any community (including the nation) knowable and visible. As writings by Hobsbawm and Ranger (1983), Anderson (1991 [1983]), and Shils (1981) have illuminated, establishing continuity with the past has been essential to the process of making a particular assemblage of people, practices, and histories into a coherent body. In a similar vein, to produce continuity with a past – that is, to produce a history – also entailed the production of place. Together these systems of representation have come together to produce the heritage of place, that is, through practices that establish social cohesion or symbolize belonging for real and artificial communities.

Nation-states, newly formed with the end of decolonization, were active in making national identities that would be projected on an international stage. Following World War II, postcolonial nations engaged in cultivating national identity in the architecture of capitol buildings (Vale 1992). Vernacular architecture has also provided another stage to cultivate national identity. Returning to Egypt, the work of the architect Hassan Fathy provides a case of heritage that was manufactured at the behest of the government. Fathy continues to be a key interlocutor of Egyptian national identity and one of its most well-cited authors of heritage. What is now deemed authentic vernacular architecture, based on traditional mud construction and the housing layouts of medieval Cairo, was indeed Fathy's interpretation and construction of those forms. In the 1940s, the Egyptian Department of Antiquities commissioned Fathy to build a model village for the inhabitants of the village of Gurna located on the west bank of the river Nile near the necropolis of Luxor. The model village of New Gurna would be a relocation site for these inhabitants. Though the village remained unfinished and the project abandoned by Fathy, New Gurna became internationally admired for its usage of local materials and Fathy for his appropriation of forms. His work continues to help define national heritage and postcolonial authenticity. In a recent twist, UNESCO set out to "safeguard" New Gurna beginning in 2011 through the restoration and preservation of the village, further cementing the authenticity of what was a manufactured heritage.

Authenticity in an Era of Global Capitalism

In the realm of architecture and urban design, the critique of high modernism coupled with the reconfiguration of capitalism and society together has renewed debates on heritage and authenticity. Heterogeneity, difference, and distance have become the hallmarks of a cultural industry that must deal with the time-space compression of global capitalism. What began as an interrogation of culture in the 1980s and 1990s in the social sciences and humanities has led to an emphasis on the politics of difference, a turn that has entailed a rejection of totalizing and abstract narratives in favor of the contingent and variable identities and spaces. Coupled with this epistemic shift has been a recalibrated role of culture in the political economy – what David Harvey (1990) has referred to as culture in the embrace of capitalism – evident in tailored projects in architecture, heritage, and urban design. If the built environment constitutes one dimension of the complex of experience crucial to forging new cultural sensitivities, the expanding importance of heritage sites as regimes of accumulation and difference making can be seen as its dialectical twin.

In looking at the question of mediation of authenticity through space, AlSayyad (2001) has noted increasing demand for built environments that promise unique cultural experiences. A countervailing weight to the intensifying flows of the global has been the revalidation of place and local difference. The manufacture of heritage supports the Marxist view on the infinite capacity of capitalism to commodify everything. Among these commodities are cultural landscapes.

Amidst the fragmentation generated by flexible accumulation and the condition of postmodernity, the identities of built environments have become new frontiers of cultivation and manipulation.

Following AlSayyad (2001), practices of manufacturing can be categorized as such: an emphasis on iconography where iconography becomes culture, the memorialization of history established through visuality, and an emphasis on the profitability rather than facticity of history. Tourism exposes the paradoxes of authenticity as an ideal and as a pursuit. On one hand, tourism is predicated on the desire for an authentic experience, to see life as it is really lived. Yet tourism, as part of the visual economy of consumption, has also been associated with the superficiality of engagement with the figure of the tourist content with inauthentic experiences. What is taken to be authentic may in fact be a performance of authenticity or indigeneity, with culture and place circumscribed, rationalized, ordered, and exploited. Representations of place – peoples, geographies, culture, and nature – are central elements to a visual economy that links the political economy of capitalism to the aestheticization of space and the appropriation of culture and history.

The city of Las Vegas represents the most explicit site of manufactured heritage where any pretense of authenticity or reality is dispensed with altogether. Here the sophisticated themed casino complexes proffer "authentic fakery" (AlSayyad 2001). Vegas boasts a fake Sphinx and miniature pyramid at Luxor, the self-contained Venice canals, and a scaled-down Arc de Triomphe and Eiffel Tower based on the mimicry of authentic places. The Brooklyn Bridge runs parallel to the Strip, and the Statue of Liberty sits on the corner of Las Vegas Boulevard and Tropicana Avenue. The 20-acre New York-New York Hotel and Casino aims to evoke the glamor of New York without the city's grit or density. As "spectacle" organizes both economy and society in the United States in general and Vegas in particular, Vegas has been able to capitalize on its ability to adapt to the demands and needs particularly of the middle class. Specific to Vegas is its characteristic malleability, its ability to brand itself anew, pointing to the absence of a fixed identity for the city. It is a place where "nothing is real" which is understood as its selling point that has ensured its viability throughout its history.

Future Directions

The authentic fakery of Las Vegas is best understood in relation to the "fake authenticity" (AlSayyad 2001) of Santa Fe, New Mexico. Santa Fe's pueblo adobe forms, though rooted in the history of the area, are in fact constructions of cement and wood disguised as adobe. The unity of appearance of Santa Fe afforded by the Santa Fe style of architecture became codified through a series of urban planning efforts in the early twentieth century. And, what is now known as the "Santa Fe style" was defined by the Museum of New Mexico in the 1910s. The city is, according to Wilson (1997: 4), "an unusually successful illusion of authenticity." The fabrication of its identity and the manufacture of Santa Fe's heritage were designed to revive the local economy through tourism.

The power of the manufacture of heritage is beautifully captured by Andreas Huyssen:

> One of modernity's permanent laments concerns the loss of a better past, the memory of living in a securely circumscribed place, with a sense of stable boundaries and a place-bound culture with its regular flow of time and a core of permanent relations. Perhaps such days have always been a dream rather than a reality, a phantasmagoria of loss generated by modernity itself rather than its prehistory. But the dream does have staying power. (2000: 34)

Authenticity continues to be a resilient trope through which locality and identity are cultivated. As the preceding discussion has shown, what determines authenticity is the frame of reference. Disneyland, the quintessentially American landscape, is a case in point. Disneyland's Main Street evokes the nostalgia for small town America. The street's design was inspired by two towns in particular, Marceline, Missouri, and Fort Collins, Colorado. Marceline was Walt Disney's boyhood home and Fort Collins the birthplace of Disneyland's first director, Harper Goff. Facing economic decline in the late 1990s, Marceline sought to further cement its fate to Disneyland and transform itself into its

official hometown. In a move that shows the circular movement of authenticity, the town renamed its Kansas Avenue to "Main Street USA" after the gateway to Disneyland Park. Many of the architectural flourishes of Disney's Main Street come directly from Fort Collins. Disneyland's City Hall is a replica of the courthouse in Fort Collins, drawn at three-quarters scale. As Fort Collins grows and attempts to preserve its heritage, it also has resorted to a process that some have called Disneyfication (Iovine 1998). Here lies the greatest dilemma for authenticity: the authentic object has to rely on its own replica to maintain its survival rendering the authentic and the replica a reciprocal pair in a continuous dynamic.

Authenticity in Archaeological Conservation and Preservation

Henry Cleere
Institute of Archaeology, University College London, London, UK

Introduction

The Pioneers

"Authentic" is defined in the *Merriam-Webster Dictionary* as "*a*: worthy of acceptance or belief as conforming to or based on fact, *b*: conforming to an original so as to reproduce essential features,

and *c*: made or done the same way as an original." This adjective derives from the ancient Greek *authentēs*, meaning "perpetrator or master." The entry for "authenticity" in the *Shorter Oxford Dictionary* (2nd edition, 1936) defines it as "the quality of being authentic," dating from as early as 1657, with four examples of specific applications: (1) as being authoritative or duly authorized, (2) as being true in substance (1762), (3) as being genuine (1760), and (4) as being real, actual (1851).

Concern for authenticity, however defined, in the approach to the restoration and conservation of historic buildings and monuments did not begin to manifest itself fully until the nineteenth century. However, the role of the painter Raphael (Raffaele Santi) in the early sixteenth century played a significant role in the conservation of the earliest surviving monuments of Rome. It was, however, the work of such pioneers as Karl Friedrich Schinkel (1781–1841) and Eugène Emmanuel Viollet-de-Duc (1814–1879) that created an awareness of the need for a systematic approach toward the restoration and conservation of ancient and historic buildings.

The early twentieth century saw the development of a more analytical approach toward the conservation and restoration of the historic heritage. Two names stand out in this theoretical field, those of the Austrian Alois Riegl (1857–1905) and the Italian Cesare Brandi (1906–1988). Following a detailed analysis of the requirements of a state monuments service, Riegl published *Der modern Denkmalcultus, sein Wesen, seine Entstehung* (The modern cult of monuments: its character and its origin) in 1903. In this he identified two main groups of values:

Memorial values (age value, historical value, and intended memorial value)

Present-day values (use value, art value, newness value, and relative art value)

This penetrating classification retains its fundamental validity up to the present day.

Brandi's work dovetails in with that of Riegl, whose classification he expanded slightly into the aesthetic and the historical. He set out three essential elements in any interventions relating to the conservation and restoration element of heritage preservation:

Any reintegration should be easily recognizable at close hand, but at the same time it should not adversely impact the unity that is being restored.

The role of material that directly results in the images is irreplaceable in so far as it forms the aspect and not the structure.

Any restoration should be made in such a way that it will not be an obstacle to subsequent future interventions – indeed, these should be facilitated.

Key Issues/Current Debates/Future Directions/Examples

The Venice Charter

Brandi's holistic approach to conservation and restoration has not always been accepted uncritically, but by and large it still constitutes the contemporary approach to the subject. He did not make use of the term "authenticity" in any of his many publications, but it is implicit in everything he wrote. The first significant use of the word seems to have been in the 1964 International Rescue Convention, produced by the Second International Congress of Architects and Specialists of Historic Buildings and best known as the Venice Charter (to commemorate the historic city in which the conference took place).

The Charter is a remarkable document, providing as it does a detailed ethical and practical framework for the conservation and restoration of the built heritage. It is interesting that the word "authenticity" occurs only once in the Charter: its preamble states that "The common responsibility to safeguard [*historic monuments*] for future generations is recognized. It is our duty to hand them on in the full richness of their authenticity." Article 9 contains the single use of the adjective "authentic": the object of restoration is defined as "to preserve and reveal the aesthetic and historic value of the monument and is based on respect for original material and authentic documents." The fact that there is no definition or explanation of this term, however, suggests that the concept was in general use by the 1960s.

The 1964 Venice conference had been convened at the prompting of UNESCO, which was moving toward the drafting of a convention on the protection of the world cultural and natural heritage. It also resulted in the creation in the following year of the International Council on Monuments and Sites (ICOMOS) with the express responsibility of applying the conservation philosophy and recommendations of the Venice Charter. With the signing of the UNESCO Convention Concerning the Protection of the World Cultural and Natural Heritage (better known as the World Heritage Convention) in 1972, ICOMOS was designated an advisory body to the UNESCO World Heritage Committee, responsible for the cultural heritage.

Authenticity and the World Heritage Convention

The practical implementation of the Convention is set out in the *Operational Guidelines for the Implementation of the World Heritage Convention*, which has been subjected to considerable modification and emendation since its first edition in 1977. That text requires that properties inscribed on the World Heritage List should "meet the test of authenticity in design, materials, workmanship, and setting." It goes on to specify that "authenticity does not limit considerations to original form and function, but includes all subsequent modifications and additions, which in themselves possess artistic or historical values." The attributes deemed to be appropriate in evaluating authenticity underwent minor changes over the following years: in 1980, for example, this included the statement that "the [World Heritage] Committee stressed that reconstruction is only acceptable if it is carried out on the basis of complete and detailed documentation on the original and to no extent on conjecture." With the recognition by the Committee in 1992 of cultural landscapes as constituting a distinct category of cultural heritage, evaluation of their distinctive character and components was added to the existing four qualities.

The current (2011) text of the *Operational Guidelines* is more detailed and more comprehensive, as the following excerpts show:

> Depending on the type of cultural heritage, and its cultural context, properties may be understood to meet the conditions of authenticity if their cultural values are credibly expressed through a variety of attributes including form and design, materials and substance, use and function, traditions, techniques, and management systems, location and setting, language and other forms of intangible heritage, spirit and feeling, and other internal and external factors.
>
> Attributes such as spirit and feeling do not lend themselves easily to practical applications of the conditions of authenticity, but nevertheless are important indicators of character and sense of place, for example, in communities maintaining tradition and cultural continuity.
>
> In relation to authenticity, the reconstruction of archaeological remains or historic buildings or districts is justifiable only in exceptional circumstances. Reconstruction is acceptable only on the basis of complete and detailed documentation and to no extent on conjecture.

This amplification of the concept of authenticity in the World Heritage context (and thereby in the understanding of the international cultural heritage community) is due primarily to a series of debates and discussions that resulted indirectly from the ratification of the Convention in 1992 by the Government of Japan. Japanese heritage experts and government officials had been aware for some time of the prevalent view outside Asia that the approach to conservation, and more particularly reconstruction, in some non-European cultures was radically different to that elsewhere, notably in Europe and North America. This perception was seen as posing a fundamental problem in the nomination and inscription of many important Asian heritage monuments.

The Nara Document

The World Heritage Committee at its 16th Meeting in Santa Fe (USA) in December 1992 identified an urgent need for a critical evaluation of "the criteria governing . . . authenticity and integrity" and called upon ICOMOS to organize a meeting of experts to that end. A 3-day Preparatory Workshop was held in Bergen (Norway) on 31 January to 2 February 1994, funded by the Norwegian and Canadian Governments. On the recommendation of ICOMOS, the Japanese Government agreed to fund a major international conference on authenticity, which took place in Nara in 1–6 November 1994.

The Nara Conference brought together 45 leading experts in the field of preservation of cultural heritage: they represented international organizations and 26 countries from round the world. Following a number of statements from representatives of international bodies, the Chairman of the conference called upon delegates in turn to define their understanding of the meaning of authenticity and its application by their organizations or countries. This revealed a startling variability between regions and latter-day cultures, which demonstrated the truth of a statement by one distinguished expert: "Authenticity is in practice never absolute, always relative" (David Lowenthal in Larsen 1995). It also underlined the need for a more specific definition of what constitute the fundamental principles of authenticity based upon the international perceptions that emerged during 3 days of papers and intensive discussions. The result of this timely and revealing meeting was the Nara Document on Authenticity, which has become the touchstone for assessing authenticity.

The main points of the Document may be summarized as follows:

> Cultural heritage diversity exists in time and space, and demands respect for other cultures and their belief systems. Where cultural values appear to be in conflict, respect for cultural diversity demands acknowledgment of the legitimacy of the cultural values of all parties.
>
> Conservation of all cultural heritages is rooted in the values attributed to it, understanding of which depends, in part, on the degree to which information sources about these values may be understood as credible or truthful.
>
> Knowledge and understanding of these sources of information, in relation to original and subsequent characteristics of the cultural heritage and their meaning, is a requisite basis for assessing all aspects of authenticity.
>
> Authenticity is thus the essential qualifying factor concerning values, understanding of which plays a fundamental role in all scientific studies of the cultural heritage, in conservation and restoration planning, as well as within the inscription procedures used for the World Heritage Convention and other cultural heritage inventories.
>
> All judgements about values attributed to cultural properties as well as the credibility of related information sources may differ from culture to culture, and even within the same culture. It is thus not possible to base judgements of values and authenticity within fixed criteria. On the contrary, the respect due to all cultures requires that heritage properties must be considered and judged within the cultural contexts to which they belong.
>
> Therefore, it is of the highest importance and urgency that, within each culture, recognition be accorded to the specific nature of its heritage values and the credibility and truthfulness of related information sources.
>
> Depending on the nature of the heritage, its cultural context, and its evolution through time, authenticity judgements may be linked to the worth of a great variety of information sources. Aspects of the sources may include form and design, materials and substance, use and function, traditions and techniques, location and setting, and spirit and feeling, along with other internal and external factors. The use of these sources permits elaboration of the specific artistic, historic, social, and scientific dimensions of the cultural heritage being examined.

The ICOMOS Ename Charter for the Presentation of Cultural Heritage

The Charter for the Interpretation and Presentation of Cultural Heritage Sites (known across the world as the Ename Charter) was approved by ICOMOS at its 16th General Assembly in Québec (Canada) in 2008. This charter deals with an aspect of authenticity that is not covered elsewhere. Its stated objective is to establish seven cardinal principles upon which interpretation and presentation, in whatever form or medium is deemed appropriate in specific circumstances, should be based. Principle 4 is directly relevant to this survey:

Preservation of Authenticity The interpretation and presentation of cultural heritage sites must respect the basic tenets of authenticity in the spirit of the Nara Document (1994).

> **4.1** Authenticity is a concern relevant to human communities as well as material remains. The design of a heritage interpretation programme should respect the traditional social functions of the site and the cultural practices and dignity of local residents and associated communities.
>
> **4.2** Interpretation and presentation should contribute to the conservation of the authenticity of a cultural heritage site by communicating its significance without adversely impacting its cultural values or irreversibly altering its fabric.
>
> **4.3** All visible interpretive infrastructure (such as kiosks, walking paths, and information panels), when deemed appropriate and necessary must be sensitive to the character, setting and the cultural

and natural significance of the site, while remaining easily identifiable.

4.4 On-site concerts, dramatic performances, and other interpretive activities – when deemed appropriate and sensitive to the character of the site – must be carefully planned to minimise disturbance to the local residents and to the physical surroundings of the site.

It remains to be seen to what extent this admirable charter will influence the interpretation and presentation of the cultural heritage in the years to come.

The Riga Charter

The Riga Charter on Authenticity and Historical Reconstruction in Relationship to Cultural Heritage, known as the Riga Charter, is an international statement of the scope, objectives, and participants in cultural heritage projects. The charter was adopted at Riga (Latvia) on 23 and 24 October 2000 at the Regional Conference on Authenticity and Historical Reconstruction in Relationship to Cultural Heritage, initiated by ICCROM.

It focuses on reconstruction and supplies additional comments on the existing provisions in this field of the Venice Charter and other doctrinal texts including the Nara Document. These as well as the UNESCO World Heritage Convention establish a presumption against reconstruction of the cultural heritage, except in circumstances where reconstruction is necessary for the survival of the property, where a property is incomplete through damage or alteration, where it reconfirms the cultural significance of a property, or in response to loss through disasters, whether of natural or human origin. Reconstruction must, however, be carried out without conjecture or compromising existing in situ remains and must be legible, reversible, and the minimum necessary for conservation and presentation. It takes note of the fact that issues of reconstruction and authenticity have become of particular concern, particularly in countries that have recently regained their independence.

The Charter contains the following definition of authenticity (Article 4):

Authenticity is a measure of the degree to which the attributes of cultural heritage (including form and design, materials and substance, use and function, traditions and techniques, location and setting, and spirit and feeling, and other factors) credibly and accurately bear witness to their significance, believe that replication of cultural heritage is in general a misrepresentation of evidence of the past, and that each architectural work should reflect the time of its own creation, in the belief that sympathetic new buildings can maintain the environmental context, but that *in exceptional circumstances*, reconstruction of cultural heritage, lost through disaster, whether of natural or human origin, may be acceptable, *when* the monument concerned has outstanding artistic, symbolic or environmental (whether urban or rural) significance for regional history and cultures; provided that appropriate survey and historical documentation is available (including iconographic, archival or material evidence); the reconstruction does not falsify the overall urban or landscape context; and existing significant historic fabric will not be damaged; and providing always that the need for reconstruction has been established through full and open consultations among national and local authorities and the community concerned.

Authenticity and Archaeological Sites and Monuments

Most debate about authenticity has tended in the past to concentrate on historic buildings. On the whole ancient structures and archaeological sites have been given considerably less attention by heritage conservators and managers. As a result there are some archaeological monuments on the World Heritage List where reconstruction has gone well beyond the strict application of the concept of *anastylosis*, and the level now considered to be "acceptable only on the basis of complete and detailed documentation and to no extent on conjecture." The creation of structures on major archaeological sites for the form of which there is little, if any, justification either in the remains themselves or in the available contemporary literature is to be found most frequently associated with so-called theme parks or similar enterprises. The number of these is happily declining, but archaeologists and heritage organizations must constantly watch out, since this can be a profitable business in the wrong hands.

In this context, ICOMOS is to be commended for its initiative in approving the Ename Charter, which, it is to be hoped, will be widely approved and adopted by the heritage community.

Authenticity in Archaeological Writing and Representation

Allison Mickel
Department of Sociology and Anthropology, Lehigh University, Bethlehem, PA, USA

State of Knowledge and Current Debates

Authenticity as a concept is integral to the discipline of archaeology. Discriminating between real artifacts and forgeries, determining secure provenance, and investigating how past actually happened are all activities at the core of producing archaeological knowledge and can be seen essentially as quests for authenticity. The idea of authenticity, moreover, takes on especial importance with regard to the writing and representation of archaeological knowledge. Since the beginnings of archaeological research, archaeologists have expressed concern regarding their ability to present the past as realistically as possible and to communicate the nature of archaeological work in an accurate way that a variety of diverse audiences will be able to understand.

However, the definitions of "accuracy," "realism," and "authenticity" as they pertain to archaeology have been in a state of near-constant change for nearly two centuries. The concept of authenticity necessitates an external or original referent which a representation or piece of writing is aiming to approximate and implies some means, however amorphous, of determining how closely the representation approximates the original. Over the course of the history of archaeology, practitioners of the discipline have defined both this referent and the criteria for authentic representation very differently. When examining examples and discussions of archaeological writing over time, there appear at least three identifiable phases in practical and theoretical expressions of the relationship between authenticity and representation in archaeology. And now, a new phase is emerging coincident with the development of digital technologies in fieldwork and archaeological analysis. Each of these phases is described and explained here, with examples from each phase and a discussion of how these phases have blurred into one another historically. The contemporary state of the relationship between authenticity and archaeological representation is also outlined, with some suggestion of what this relationship is likely to develop into in the near future.

For most of its early history in the eighteenth and nineteenth centuries, archaeological work was characterized by a pursuit of authenticity in the sense of verifying facts and rendering a more accurate story of the past. This ambition was perhaps best expressed in the first issue of the journal *Archaeologia*, the longtime flagship

publication of the Society of Antiquaries of London. In a preface to its first issue, the editors wrote that

> "the History and Antiquities of Nations and Societies have been objects of inquiry to curious persons in all ages, either to separate falshood from truth, and tradition from evidence, to establish what had probability for its basis, or to explode what rested only on the vanity of the inventors and propagators" (1770: i).

Expeditions and excavations began in earnest, accordingly, to tie the accounts from ancient texts to real places and object assemblages. Archaeologists explored and dug in order to identify cities mentioned in the Bible and in classical writing. They worked as well to recreate prehistoric periods known only from happenstance finds. And, from the earliest meetings of the various European scholarly and antiquarian societies, these researchers "had formed a design of communicating their discoveries to the public" (1770: i).

In order to succeed in this design, archaeological researchers working in the eighteenth and nineteenth centuries published both letters and memoirs describing their findings and experiences while recovering direct evidence of the past. The letters were initially sent to excavation sponsors or fellow members of scholarly societies. Letters were later bound together and published as volumes of the societies' journals. Memoirs, meanwhile, were composed with a public audience in mind from the start and worked to tell the complete story of an archaeological expedition, offering a satisfying narrative with a clear beginning, middle, and end. Being highly personal, both of these early forms of archaeological publications communicated extremely vivid and emotive perspectives on the work that they reported (Hodder 1989). They were written in first-person voice and dramatically guided the reader through the moment-by-moment thought process of the author. The reader would learn about difficulties encountered, periods of uncertainty, and lingering questions that make the breakthroughs, discoveries, and advancements in knowledge all the more exciting. These documents acted as thick descriptions which recreated the total and sensational experience of excavation, offering a vicarious engagement with the work of archaeology.

Expeditions from this time period also enlisted the work of specialized draftsmen and architects responsible for drawing the monuments, remains, and objects discovered over the course of the archaeological research program. Expertly drawn and detailed, these images published particularly in the memoirs of early archaeologists added to the veracity of the archaeological text (Molyneaux 1997; Moser 2012). Over time, visual conventions and codes developed, and these sorts of images – in distinct black and white lines, carefully shaded and drawn to scale – conveyed a neutrality and reliability essential to the goal to distill facts from fables. Many publications from this time period additionally included drawings of reconstructed scenes, imagining a building or settlement as it would have looked when inhabited in antiquity and featuring depictions of living people in ancient costume. Like the vivid detail in the text itself, these kinds of science-based reconstructions enhanced the relatability of archaeological representations from this early period, expanding the immersive quality of archaeological fieldwork and projecting it into the past. Both the writing and the visual representations contained in early archaeological works surrounded their readers with sensory detail that communicated an overabundance of facts but through a deeply human and personal lens.

At the same time, however, the coverage of the material objects retrieved through these early excavations remained almost purely descriptive (Connah 2010; Sinclair 1989). While the methods and process of the excavation were expressed in enthusiastic, sensational terms, the artifacts and archaeological deposits were presented and illustrated without passion. Indeed, writers of this early time period generally resisted attempting to extrapolate about the past or to draw conclusions about ancient lives and societies based on the assemblages they recovered. They instead conformed to what Anthony Sinclair (1989: 221) has called translating the museum into text or what Graham Connah (2010: 21) has termed the "laundry list" approach – a dense inventory briefly mentioning a number of the significant things found during the research process. Stylistic and

artistic details might be provided, along with basic measurements, but there was no contextual analysis or historical conjecture about the original uses or meanings of these objects.

The archaeological text from the first two decades of the discipline, therefore, aimed at two simultaneous authenticities. The first was an authentic representation of the past, based on concrete archaeological evidence – the elimination of exaggeration, distortion, or aggrandizement from shared ideas about historical civilizations. This was, after all, the underpinning of the archaeological scholarly societies established in the eighteenth century. It was this type of authenticity that the descriptive lists of objects targeted, attempting to eliminate room for error or problematic personal bias.

Meanwhile, the second form of authenticity that these narratives aimed to accomplish was a realistic and relatable recounting of the processes of exploration and excavation. This second authenticity centered on one's ability to share the full experience of the fact-finding endeavor, to enable a reader to envision the voyage, from beginning to end, from inside the author's body. And whether the authors themselves explicitly recognized it or not, the storytelling in early memoirs of archaeological undertakings was rife with artistic exaggeration and poetic flourishes (Hodder 1989; Connah 2010).

It is worth noting that these two forms of authenticity are in many ways opposed to one another. While the first involves taking an established conceptualization of the past and stripping away everything for which there is not tangible, identifiable evidence, the second form of authenticity requires building up a story from intangible memories, interactions, and encounters. The first is reductive, the second additive. In the writing dating from this time period, authenticity took a radically different form depending whether it was the distant or immediate past being represented. The authentic representation of the distant past, the past of antiquities, necessitated a commitment to exactitude in narrative, data description, and visualization. But the authentic representation of the more direct past – the recently concluded archaeological work – required an account so thoroughly and vibrantly descriptive that one could imagine oneself to have experienced the thing itself. There is a dichotomy – even a friction – between the authenticity entailed in representing the archaeological past in early archaeological writing and the authenticity involved in representing the archaeological endeavor.

This dichotomy, however, diminished in the mid-twentieth century. The trends in and discourse around archaeological writing followed broader disciplinary trends through the advent of processualism and New Archaeology. The movement toward emphasizing positivism and hypothesis testing transformed the nature of authenticity that archaeologists sought to achieve in their writing and therefore transformed archaeological writing itself. The processual movement brought about an increased suspicion around subjective, individual experience, instead seeking transportable middle-range theory and universal laws applicable to many sites and regions. This shift also emphasized rigorous methodologies and making fieldwork as reproducible as possible (while acknowledging that archaeological excavation cannot be repeated).

Amidst this transition in the discipline of archaeology, the aim of rendering an accurate, and therefore authentic, portrayal of the past persisted from the early phases of archaeological writing through the periods of processualism's major influence. In representing the past, archaeologist-authors still emphasized direct evidence and avoided speculation and elaboration in narrative form as much as possible. Technical drawings, photographs, data tables, and charts appeared in greater and greater numbers to supplement direct and comprehensive descriptions of archaeological assemblages, adhering to strict disciplinary scientific codes (Molyneaux 1997; Moser 2012).

This is not to say, however, that the representation of archaeological assemblages obeyed precisely the same ideals as in earlier periods. Interpretation of archaeological remains was now welcomed rather than categorically avoided, but any interpretation needed to be firmly motivated by demonstrated rules based on, for

instance, experimentation or ethnographic analogy. The analysis of archaeological objects followed the scientific method, proposing and testing hypotheses, utilizing mathematical models whenever necessary and possible, and summarizing findings in a dispassionate manner. See, for example, Walter Taylor's admonishments to archaeologists before him, which became an influential aspect of New Archaeology:

> It behooves the archeologist not to maintain the untenable position of 'sticking to the facts,' meaning the renunciation of inference, hypothesis, and testing. It rather is incumbent upon him to derive his observational data as objectively as possible, to differentiate between observed fact and derived inference, to make explicitly labeled interpretations of as detailed and full a nature as possible, and then to look, either in the ground or among the data at hand, for more evidence by which his hypotheses may be tested. Thus, more interpretation is called for, not less! (Taylor 1983: 115)

Something that changed quite dramatically from the earlier examples of archaeological writing was that practitioners of positivist or processual archaeology tended to narrate their own work in an equally straightforward and empirical way. No longer was an authentic depiction of archaeological work reliant on recreating one's particular and personal experience of the excavation process. The believability of a site report did not anymore inhere in the reader's ability to relive the total experience, but rather in stripping away subjectivity and emotive response. Processualism applied the same standards of authenticity to writing about the archaeological endeavor that early archaeologies applied to writing about antiquities and history. For instance, the pioneer of processual archaeology Lewis Binford wrote in several essays about the problems with implicit biases in anthropological and archaeological writing (1972). He instead praised "scientists" who "make their assumptions explicit and are ready to defend their arguments within an explicit logical framework" (1972: 7).

Changes in archaeological documentation during the excavation process supported this movement away from subjective experience in representing the archaeological process. It was during this same period of time that preprinted recording forms, or pro forma, entered the discipline and rapidly became an essential component of nearly every field excavation (Pavel 2010). Free-form site notebooks endured as a recording medium, but most often as supplementary to the pro forma archaeological record. Instead, preprinted sheets with defined prompts, multiple-choice questions, and circumscribed areas for responses became a mainstay on scientific archaeological excavations. The conformity of these forms unified archaeological recording, creating a more comparable and consistent body of data than the letters and diaries that served to document archaeological findings in the early phases of the discipline.

This emphasis on similarity over idiosyncrasy similarly transformed the rhetoric of archaeological publications. Instead of first-person narration, site reports became almost exclusively written in third-person voice or from the perspective of an ambiguous, often unnamed "we" (Gero 1996; Hodder 1989; Spector 1993). The excavation procedure was made to sound natural and self-evident; the confusion, happy successes, and despairing failures were evened out. Along with this emotive flattening and dispersal of personal perspective came the elimination of discussions of uncertainty and yet-to-be-answered questions. Site reports followed a conventional format or template, including a discussion of the location of an excavation, hypothesis, a detailed account of methods, presentation of data, and analysis of the results motivated by as universal interpretive rules as possible.

In the on-site recording strategies, in visualizations and illustrations, and in post-excavation publications, then, there was an appeal to a consistently defined authenticity through the period of processualism's greatest influence in archaeology. All of these records worked to represent, as accurately as possible, *both* the excavation process and the archaeological past in a way that any observer would agree on. The referent for authentic archaeological writing was objective reality in the past and in the present. Archaeologists in this tradition believed, therefore, that they were all writing about the same thing – the same past and the same way of knowing about it. Accordingly,

archaeological writing developed strict conventions designed to aid archaeologists in writing unified narratives. If archaeologists were writing about the same things, adhering to the same rules and values for both excavation methodology and archaeological interpretation, then their accounts should look remarkably similar. And they did (Hodder 1989).

Starting in the late twentieth century, however, scholars across the humanities and social sciences began asking questions motivated in large part by postmodernism. These questions challenged hegemonic claims to objective reality, instead emphasizing positionality, subjectivity, and the construction of reality. In anthropology, this influence can be seen especially in the concerns expressed by the authors of *Writing Culture* (Clifford and Marcus 1986) who confronted the norms of traditional ethnographic writing. They argued that traditional tropes and styles claimed an unjustified scientific authority. They suggested experimentation and greater creativity in anthropological writing could lead to new, innovative, and more convincing representations of other cultures and communities. More thoughtful and inventive writing forms could in turn appeal to a different sort of authenticity, one based on a poetic resemblance or proximity to the lived experience of ethnographic fieldwork.

In the 1980s and 1990s, archaeologists began to express similar points of view. In 1988, James Deetz stated that "archaeologists are increasingly expressing concern over the positivist view that objectivity can be achieved" and characterized "pure unqualified objectivity" as "beyond our reach" (Deetz 1988: 16). In the same year, Paul Courbin (1988: 80) argued that archaeology is "far from a really 'scientific' procedure and from conclusions that are above all suspicion." A decade later, critiques of positivism sharpened; Adrian Praetzellis, for instance, described "throwing positivism out the window" as "liberating" (Praetzellis 1998: 1). Notably, his comments appeared in a volume of *Historical Archaeology* devoted entirely to the subject of storytelling in archaeology.

In place of positivism, many archaeologists (along with social scientists and humanists from other disciplines) argued that the knowledge generated through archaeological research is constructed rather than simply uncovered. There is, they asserted, no objective truth that archaeologists discover; instead, individual human archaeologists, through imagination and dialogue, create stories about the past based on fragmentary evidence. According to those who promoted this constructivist view of archaeological knowledge, all of the decisions made by researchers and excavators throughout the archaeological process were shaped by the particular interests, priorities, and subjectivities of those people. Ian Hodder, an advocate for this point of view, described, for example, the range of different criteria that one could viably choose in order to categorize a deposit of soil as a single layer (Hodder 1999). One could look at, for example, the color of the soil when dry, the color of the soil when wet, the color of the soil at a given time of day, the texture of the soil, the feel against the trowel, the sound against the trowel, the smell of the soil, and even chemical analysis. Hodder argued (1999) that there are a similar range of choices available for every step of the excavation process from site definition to artifact recovery to data entry to laboratory analysis. Deciding which decision-making criteria to use in any given excavation, and at any particular moment, determines at an elemental level what is preserved in the archaeological record, shaping future analysis and the ultimate content of archaeological knowledge.

This skepticism around the possibility of positivism and applicability of empiricism to the archaeological process was a crucial motivation underlying the development of postprocessual archaeologies (Shanks and Tilley 1987). As close examination of the archaeological process revealed how essential subjective perspectives were to every dimension of that process, and as anthropology more broadly tested the relevance of objectivism for ethnographic writing, postprocessual archaeologists increasingly raised similar questions with regard to archaeological writing in particular. Joan M. Gero rebuked the forms of archaeological writing which had by now become conventional for "deliberately obscuring the practical organization of knowledge construction" and for implying through passive language and scientific language that "anyone would have

come to the same conclusions" (Gero 1996: 257). Rosemary A. Joyce expressed a similar critique, looking in particular at passive scientific phrasing common in archaeological writing – sentences such as "the figurine cache suggests. . ." (2002: 117). This is problematic, she asserted, because through this language archaeologists attribute their own voices and interpretations to the artifacts themselves. The conclusions – indeed, theories and hypotheses – described in this way are made to sound as if they were pulled out of the ground in a form as concrete as the physical assemblage.

The postprocessual critique of conventional archaeological writing took aim at the ideas about authentic archaeological writing advanced by processual archaeologists. Rather than seeing scientific language and formats as the most effective means of communicating accurately and precisely, postprocessual archaeologists argued that this mode of writing was decidedly *inauthentic*. The language of objectivism, they maintained, artificially removed the people from excavation narratives and interpretations of the past. It masked the interpersonal character of excavation, the full range of influential factors on decision-making and interpretation – in essence, the *real* process of knowledge production in archaeology. Postprocessual critiques of archaeological writing argued that instead of purifying narratives of the research process and descriptions of the archaeological past down to its most basic, secure, and truthful form, traditional styles of writing in archaeology presented distinctly partial and false accounts of history and how archaeologists study it.

Instead, they argued for a fuller depiction of the archaeological process and the conjecture and uncertainties regarding the archaeological past. Recreating the archaeological experience more accurately necessitated alternative forms and languages in archaeological writing. Remarkably, what they were advocating more closely approximated the letters, diaries, and memoirs of archaeology's earliest periods, at least with regard to descriptions of the research procedure (Hodder 1989, 1999; Joyce 2002). They were looking for the same emotional content, sensory experience, pitfalls, human interaction, and vivid context that early archaeological writing provided. But it was not only with regard to the archaeological process that they argued for such a more vibrant representational approach. For many postprocessual archaeologists, writing about the distant past should feel similarly immersive, relatable, and open to interpretation.

There are, then, three broadly identifiable phases in the relationship between authenticity and archaeological writing through the history of the discipline. The first, from the early period of archaeology, distinguished between the distilled authenticity of impersonal descriptions of archaeological objects and the authenticity of a vividly and creatively narrated archaeological process. In the second phase, during the dominance of processualism, archaeologists pursued nearly exclusively the former sort of authenticity, seeking objectivity and the abolishment of bias in both the interpretation of archaeological remains and the presentation of the excavation process. Then, in the third phase, postprocessualists encouraged quite the opposite, advocating for an embrace of subjectivity and sensory experience in descriptions of archaeological fieldwork and in the analysis of the archaeological record.

It is essential to note, of course, that as with any attempt to draw distinct chronological periods, these phases blur and fold into one another. An example of this is the work of R.G. Collingwood, who published multivolume corpora of inscriptions and highly descriptive accounts of Roman sites and assemblages in the United Kingdom. His 1930 text, *The Archaeology of Roman Britain*, for instance, contained comparative plans of towns and military forts along with typologies evoking the level of detail and comprehensive coverage of a museum index. It appeals to the sort of authenticity of the earliest archaeological practice – the direct museum-like description of assemblages of objects and archaeological remains. Collingwood, however, as a philosopher of history at the same time argued that historical events and lifeways cannot be directly observed – and significantly, that the thought processes and experiences of people in the past are impossible to access (Collingwood 1946). Accordingly, Collingwood maintained that those who study the past must use their imaginations to "reconstruct" historical events and the perspectives of past actors on

those events. His attention to the activities and hermeneutic processes of contemporary scholars of antiquity and in particular his argument that there is always, inevitably, a separation between the past as it actually happened and history as it is interpreted in the present resonate strongly with the arguments of the postprocessual movement in archaeology. Ian Hodder (1995) has in fact cited Collingwood's work as a major inspiration for the arguments of postprocessualism regarding the active and constant interpretation involved in the excavation endeavor. Collingwood as an archaeologist may have appealed to the sort of authenticity common within archaeology of his own time period while anticipating the arguments about positionality and authenticity characteristic of archaeology in the late twentieth century.

Kent Flannery's work similarly evinces the imperfection of delimiting three distinct phases in the dynamic relationship between archaeological representation and authenticity. Flannery advocated for the expanded application of systems theory in archaeology, based on the argument that conceiving of culture as a system consisting of elemental parts enables archaeologists to examine those elemental parts using objective mathematical models (Flannery 1968). His explanation and elevation of systems theory was influential within the processual movement, appealing to processualism's search for universalism and empiricism. An approach which ideally could be applied equally to any site in any place, from any period, conformed to that pursuit of identifying and resolving bias, subjectivity, and idiosyncrasy central to mid-twentieth-century archaeology. Meanwhile, however, Flannery is well known for experimenting with extremely creative writing styles – styles very distant from the straightforward presentation of assumptions and "explicit logical framework" that Binford championed. He experimented with fictional writing, in particular fiction that blurred the boundaries between reality and imagination. His 1976 volume *The Early Mesoamerican Village* illustrates his dual commitments to an authentic representation based on scientific objectivity and one based on a full and nuanced depiction of dialogue and debate. In it, he spends ample time discussing scientific methods, research design, and in particular the adequacy of various sampling strategies. At the same time, he creates three distinct exaggerated characters representing the conflicting interests and goals between which any archaeologist must mediate over the course of the excavation process. "The three allegorical characters introduced in the parable," Flannery says, "are all part of one personality. All of us engaged in Formative archaeology have varying degrees of each – skeptical graduate student, real Mesoamerican archaeologist, and great synthesizer – carrying on a dialectic inside our heads" (1976: 4).

Flannery's emphasis on indeterminacy, on emergent ideas, and on dialogue foreshadowed postprocessualists' concerns with these same issues as they recognized the essential role teamwork and communality play in the production of archaeological knowledge (Hodder 1999; Joyce 2002). His willingness to break with traditional archaeological writing formats signaled changes to come. The 1990s saw an explosion of unconventional archaeological texts, many of which employed real and imagined dialogues like Flannery's allegory to illustrate the centrality of discussion to the archaeological endeavor. Ian Bapty's "The Agony and the Ecstasy" (1990) presented an imagined conversation between three characters: Bapty's own Inward Voice, his Outward Voice, and the silent, invisible Past. While the Outward Voice speaks like a scholar, employing technical vocabulary and complex syntax, the Inward Voice criticizes the Outward Voice for speaking in such a flat, unemotional way, encouraging the audience to consider the irremovable influence of any given author's personal perspective in his work. Adrian and Mary Praetzellis's "A Connecticut Merchant in Chinadom" (1998) also took the form of a play. Their script put a fictive archaeologist into dialogue with the subject of her work during the archaeologist's presentation at the annual Society for Historical Archaeology conference.

Other dialogues placed real archaeologists in conversation with one another. Ruth Tringham's "Households with Faces" (1991) included what she called a "radio story" imagining a conversation between herself, Marija Gimbutas, Ian

Hodder, and Andrew Sherratt. Her purpose was to illustrate that each of their divergent viewpoints made significant and complementary contributions to the discipline's knowledge of prehistory, not only individually but more importantly when they confronted and dovetailed with one another. Further emphasizing the centrality of dialogue and debate to archaeological writing coming out of this tradition, other texts reprinted conversations between archaeologists that actually transpired. Rosemary Joyce's *The Languages of Archaeology* (2002) was an example of this, as was Barbara Bender's *Stonehenge: Making Space* (1998). Both present actual, if slightly edited, email conversations between archaeologists whose consensus, disagreement, and collaboration led to the texts in their published form.

Plays and published dialogues like these evinced postprocessualists' interest in generating novel ways of making clear the interpretive processes of archaeology and particularly in unmasking the aspects that had previously been hidden underneath the rhetoric of positivism. Breaking free from the constraints of scientific writing conventions, for these writers, enabled a truer presentation of how conclusions were actually being reached through the archaeological research process. And, at the same time, archaeologists were similarly dissatisfied the way that dry, scientific descriptions of the past understudy did not reflect the cognitive, cultural, and sensory experiences of historical communities which interested many archaeologists. Simultaneous with the proliferation of creative writing forms illustrating the complexity of archaeological knowledge production, then, came a parallel proliferation of creative writing concerning the archaeological past.

Roderick McIntosh, for instance, in *Peoples of the Middle Niger*, alternated scholarly discussions of archaeological and historical evidence with chapters of fictional narrative, which he called "historical imagination" (1998). Mark Edmonds did the same in *Ancestral Geographies of the Neolithic*, in order to allow for a more complex image of "the character of life at the time" (1999: x). Both constructed immersive experiences of multisensory worlds, attempting to capture more fully the lived experience of the communities that they study through archaeological evidence. Mary Beaudry's "Farm Journal" presented fictional journal entries composed by Beaudry (or, as she says, "discovered" (Beaudry 1998: 20)). The journal entries were based on one real diary kept by a resident of the site she is analyzing, together with "a variety of documents, a data-rich archaeological record, and [her] own imagination" (Beaudry 1998: 20). They presented well-informed but imagined first-person perspectives on everyday life at the site examined in the text, offering details that are rich, emotive, and oftentimes mundane – allowing the writing to fill gaps left by the fragmentary archaeological record. Perhaps the most influential example of an academic fictive approach to writing the archaeological past is Janet Spector's landmark book *What this Awl Means* (1993), which followed a single artifact – an awl – from its creation to its eventual deposition when it is lost by a Dakota girl. The story was made up, but was grounded in the total scientific knowledge available about Dakota life at the time. Spector's book was extremely emotional and used the Wahpeton language to enhance the atmosphere of her story. Texts such as these, presenting imagined pasts based on material archaeological evidence, demonstrate the aim of postprocessual archaeology to approach a more total and sensual representation of the archaeological past.

Some writing of this kind intermingled fictive approaches to writing about both the archaeological past and the process of archaeological reasoning. In addition to Tringham's "radio story" in which real archaeologists had an imagined conversation about actual archaeological evidence, her chapter "Households with Faces" contained a section entitled "Fantasy>Fact" in which she imagined the experience of a woman living in Neolithic Opovo (contemporary Serbia), watching her house burn after a man's death. The narrative shifted from third-person voice to first person and presented a stream of consciousness of sensory experiences ("My hair's scorching. It makes my eyes water. I'm crying!" (Tringham 1991: 124)). Carmel Schrire, in *Digging through Darkness* (1995), also evocatively wrote the past, attempting to give her audience a direct and personal experience of the archaeological period understudy. She employed invented

"testimonies" – fictional documentary sources which could have been created by the people living at Oudepost, the South African site she examines in her book. She included these to add "texture" – a sense of authenticity – to her historical analysis (Schrire 1995: 157). But Schrire's description of the archaeologists involved in the excavations at Oudepost was similarly rich, full of details about their appearances and personalities. Her narration of the excavation proceeded in a way so that the reader could see how the idiosyncrasies of the archaeologists involved bore on the ultimate knowledge created through the research process. Indeed, Schrire called the book as a whole – containing as it did accounts of both the distant past and of the archaeological process – "a collection of fictions" (Schrire 1995: 10).

Examples like these illustrate how intertwined were archaeologists' concerns with conveying the full complexity of both the distant past and the archaeological process. Paying attention to the total human experience of one necessitated similar attention to the representation of the other. These were twin concerns with the potential distortions of an objectivist lens in archaeological writing, twin concerns with an authentic presentation of the context and human experience of past and present.

It may seem oxymoronic that this pursuit of authentic representation in archaeology turned toward writing fiction and imagined dialogues. But advocates for and practitioners of these sorts of creative writing styles argued that they in fact more accurately – more authentically – reflected the archaeological encounter. For one thing, the writing tropes of fictional writing allowed for the foregrounding of both the interpersonal interactions that characterize archaeological work and the imaginative extrapolation from secure archaeological evidence (Hodder 1999; Joyce 2002). They permitted a first-person narrator, a human being present in the manuscript, responsible for the analysis presented, rather than an abstract "we" or "they." The flexible temporality inherent in fictional writing enabled an exploration of the shifting and often difficult-to-reach time scales involved in archaeological research (Joyce 2002). Furthermore, fictional writing allowed a direct illustration of how entangled data collection, interpretation, storymaking, and publication are within archaeological research (Hodder 1999). For these reasons, borrowing writing styles from fiction authors was ideal for authentically capturing the aspects of reality postprocessualism emphasized.

Even though accurate representation has always been an aim in archaeology, through shifting standards as to what "accurate" has meant across the history of the discipline, it was only during the 1980s and 1990s that archaeologists paid substantial, explicit attention in their theory and publications to writing. This period saw a dramatic expansion in the amount of archaeological writing *about* writing, at the same time that anthropologists were also writing about writing. Experimentation with creative forms of expression across disciplines represented a practical application of more abstract theoretical debates regarding narrative and writing.

But those theoretical debates have largely subsided in recent decades, both in archaeology and in related academic disciplines. Writing, representation, and authenticity are no longer such key foci, no longer generate impassioned defenses of objectivity versus positionality and personality. Within archaeological literature, the concepts of materiality and ontology have recently supplanted issues of text and representation as the major theoretical arenas. At the same time, attitudes in archaeology regarding the notion of authenticity have changed quite dramatically. More archaeologists now question the very notion of authenticity – whether it is helpful, whether it is even possible, and whether it can in fact be damaging as an ideal goal for cultures, objects, and representation in archaeology (Graves-Brown 2013; Jones 2010; Myrberg 2004). The notion that authenticity is unchanging and attainable has been thoroughly challenged, while the opposite idea – that authenticity is wholly socially constructed – is claimed to be problematic for its failure to explain the prevailing importance of authenticity for archaeologists and members of the public.

Instead, archaeologists are today embracing a broadening range of digital technologies for archaeological excavation, analysis, and presentation of results. The debates surrounding these

technologies by and large acknowledge that these technologies produce virtual realities and approximate models that can never replace the real, original source (Barceló et al. 2000). They might be considered, following Adam Rabinowitz (2015), "digital surrogates." This term, Rabinowitz has emphasized, necessitates an awareness that a digital representation of an object, deposit, or site may be extremely faithful, may be capable of providing as direct an experience of the original as possible, but at the same time, "the digital 3D model is not a true surrogate for the original... digital surrogates in particular have their own independent reality as objects or works requiring their own documentation and explanation" (Rabinowitz 2015: 35–36). Virtual records and representations in archaeology, as in any setting, are produced through a series of decisions, according to a set of priorities established by teams of human researchers. Accordingly, it is essential not to lose sight of the insights achieved through archaeological inquiry into writing and fiction regarding the importance of documenting decision-making and exploring subjectivity.

But the relationship between authenticity and digital archaeological representation does not end with a reemphasis on the same problems and solutions raised within the discipline at the end of the last century. Much of the allure of virtual reality in archaeology rests in its capabilities that transcend traditional means of documentation and representation – and even, in many ways, the real thing. Digital and 3D models can be manipulated and measured in ways that excavated remains cannot, even during the excavation process. One can alter the lighting conditions, look at structures upside down, zoom in and out, and run algorithms and computer models to test hypotheses about resource availability, lighting conditions, acoustic conditions, hydrology, climate, and a wide range of other topics. These capabilities imbue virtual archaeology with characteristics of what Jean Baudrillard called "hyperreality" (Gillings 2002; Baudrillard 1983). According to this view, digital simulations and models in archaeology create a reality that is in many ways substantially, materially different from the real referent – not necessarily in terms of factual basis, but certainly in terms of affect, aura, and affordance. These virtual technologies invite a qualitatively different experience of the archaeological record. The notion of hyperreality can be seen quite clearly in the capability of digital technologies to create immersive reconstructions of damaged archaeological sites and tangible, printed copies of unique artifacts, especially ones that have been destroyed. With these new and continually developing technological abilities, archaeological representation can in fact transcend the limitations of the real, physical archaeological record.

As digital archaeology becomes less of a subfield of archaeological practice and becomes instead the status quo, the definition and role of authenticity will accordingly change as well. As Mark Gillings has stated in his discussion of the relation between virtual reality and authenticity in archaeology:

> "The standards we use to judge the veracity of any claim to realism are fluid and inherently historical... Authenticity is not solely a property of form, but is instead a property of process and a relationship, or connectedness, between people and the world" (Gillings 2002: 25).

The new capabilities of digital technologies in archaeology transform this relationship. It seems that archaeology, therefore, is entering a fourth phase in what it deems to be "authentic" representation – a phase characterized by a challenge to the notion of authenticity itself. This phase questions whether it is possible to do better than pursue authenticity, to produce something which holds more potential than accurate documentation and publication. It retains from earlier periods the commitment to scientific precision and evidence-based reasoning, as well as the prioritization of preserving the total means by which a given perspective on the past was produced. Archaeologists seem now to be blending, therefore, the key concerns raised over the course of the discipline's development in their presentation of archaeological remains. The definition of authenticity as it relates to archaeology, having been in constant flux throughout this history, is once again being renegotiated in ways that are likely to have significant and lasting impacts for the future of archaeology.

A

Authority and Legitimacy in Political and Social Archaeology

Gustavo Verdesio
Department of Romance Languages and Literatures, University of Michigan, Ann Arbor, MI, USA

Introduction and Definition

Authority is, according to the dictionary included in Mac computers: "the power or right to give orders, make decisions, and enforce obedience." It is also "the power to influence others, esp. because of one's commanding manner or one's recognized knowledge about something," as well as "the confidence resulting from personal expertise." There is yet another meaning of this word: "a person with extensive specialized knowledge about a subject; an expert."

Whereas somebody is legitimate when he or she is "conforming to the law and to rules," archaeology is legitimate when it operates according to the legal system that regulates social life in a State and when it follows the rules it defines, as a discipline, for the practice of the profession. Despite the differences between these concepts, it is evident that they are closely related: archaeology's authority emanates from, among others, its own legitimacy. However, there are other, more important and more ancient sources for its authority.

Key Issues/Current Debates/Future Directions/Examples

Archaeology has the authority to talk about humankind's past through the study of the material culture of societies of yesteryear. It is the voice of the experts (those mentioned by the dictionary) on that matter, and in order to be able to be considered one, the individual needs to have obtained a formal education (with degree and all) in a University. As a discipline, then, it seeks to produce knowledge founded upon rules and

protocols that underlay its academic practices, and in order to learn to do that well, it is necessary to get a formal education. In Randall McGuire's opinion, archaeology is above all a craft, which means that its practitioners need to acquire not only the aforementioned knowledge imparted by institutions of higher education, but also a series of motor skills that allow them to actually put that knowledge into practice (McGuire 2008: 85).

This situation of privilege is in manifest conflict with the worldview and opinions of other social groups, especially in those countries where different ethnic populations co-exist. This scenario becomes really tense when archaeologists show little interest or respect for the opinions offered by indigenous groups. As a matter of fact, archaeologists have total control over their investigations and they can unilaterally pick and design their research agendas – which in general benefit the scholar's career and very rarely favor indigenous demands or needs. This, according to Jeffrey C. Bendremer and Elaine L. Thomas, can be described as a colonial situation (Bendremer and Thomas 2008: 60). Whether this is an appropriate classification or not for postcolonial societies, the truth is that this kind of situation comes from a power differential similar to the one described by Edward Said in his study about Orientalism: it is an asymmetric distribution of power that makes it possible for a group to elaborate a dominant and authoritative discourse about another group, and not the other way around (Said 1978).

Although it can be argued (successfully, I suspect) that, in the framework of postcolonial societies formerly dominated by colonial powers, it is not quite right to qualify the situations of oppression as colonial or colonialist; it is true, though, that in the past they were so. That is, the present-day situations of oppression are the product or the consequence of colonial legacies: the legacies left by the different colonial situations of the past, and also the epistemological frameworks from which scientific authority emanates developed, as Walter Mignolo has convincingly demonstrated in *The Darker Side of the Renaissance*, in an era that is normally characterized as early modernity or the Renaissance, but which we forget is also a colonial one (Mignolo 1995). According to this author, the traits of Modernity that are usually celebrated (scientific progress, emancipatory drive, and a long etcetera), are just the reverse (the dark side) of the colonial endeavors that took place during the first stage of European expansion. It is probably not an exaggeration nor an imprecision to suggest that the authority archaeology enjoys in the present has its origin in the prestige that surrounded science and knowledge production in the societies that emerged from the European expansion of the sixteenth century. The societies that together are known as the West are the dominant ones, as is well known, in the realm of knowledge production – the protocols, rules, and practices that characterize modern science originated and developed in them. This is a group of societies that expanded throughout the whole planet, carrying with them not only the seeds of capitalism but also a worldview based on a scientific and philosophical approach that finds its foundation in Cartesian assumptions about subject and object, mind and res extensa, and other equally foundational dichotomies (Londoño 2010: 382). From that matrix emerges not only the paradigm of modern science, in general, but also the archaeological paradigm known as New Archaeology or processual archaeology, in particular. As is well known, this new way of doing archaeology presented itself as truly scientific. Therefore, its myth of origin, according to Gavin Lucas, was to imagine itself as a conscious and scientific practice (Lucas 1995: 37). Some of archaeology's prestige and authority stems from its claim about having objectivity, universality, and exteriority as its foundation (Gnecco 2006: 82). This is why one of the most important sources of authority for the discipline is, as mentioned above, Western education and its institutions (Gnecco and Ayala Rocabado 2010: 32). And it is so, among other reasons, because scientific discourse was very useful for the administration and control of populations in the periphery (Funari 2006: 74).

The authority of the discipline comes, also, from its role in the task of building national narratives, both in the countries that endeavored the colonial enterprise and in those that emerged after being colonies of the former. According to Ian Hodder, the "scientific" archaeology (my quotation marks) that develops in the nineteenth century was made

possible thanks to the State's interest in finding ways to control historical heritage (Hodder 1999: 170). In the same vein, Wilhelm Londoño avers that archaeology was (and is) a very useful dispositif that confirmed the success of the modern project; that is to say, it confirmed the dissolution of indigenous peoples' communal ties and the discontinuity between the indigenous peoples of the present and their pre-contact ancestors (Londoño 2010: 392). This kind of statement proffered by the discipline explains why it played such a fundamental role in the dispossession of indigenous lands: because archaeology declared them dead or vanished, it made it possible for those lands to be left at the disposal of the State and private interests (Haber 2010: 56).

In the countries of what today comprise central capitalism, such as the United States and those of Europe, archaeology is strongly related to a social class, in spite of the claims about being an objective science that characterize the discipline's spokespersons since the advent of the New Archaeology. As a matter of fact, the birth of the modern Nation-State is specifically tied to a social class, the bourgeoisie, that needed the help of archaeology and other disciplines to both legitimate that experiment in State organization and to rewrite the past of human occupations of the territory (Trigger 1989). It should be also pointed out that, as McGuire suggests, in the countries where settler colonialism developed, archaeology has become a neo-colonial endeavor, because it has dedicated itself to write the history of the ancestors of present-day indigenous peoples by the descendants of the settlers (McGuire 2008: 77–78), while in more recent times it has become a strong ally of the segment of society known as the middle class in both Europe and the United States (McGuire 2008: 88) – and it can be argued that this has happened in other parts of the world as well.

From the 1980s, however, archaeology has had to face a series of challenges undertaken by individuals coming from social groups that do not feel represented by the rules, epistemological assumptions, protocols, practices, and the knowledge produced by the discipline. The bourgeois, Europeanized, and masculine nature of archaeological practice could not continue to pretend to be an objective view of humankind's material past. Its practices, which were dedicated, from its beginnings as a discipline, to favor the interests of the dominant segments of society, began to be rejected from several fronts. Those criticisms were grouped in an umbrella concept known as postprocessualism, which as a multi-headed Hydra attacked, from different angles, the fundamental tenets of processual archaeology. Among the different, new ways of doing archaeology, one, indigenous archaeology, deserves special mention. It is a practice that proposes to take into account the interests, desires, and opinions of indigenous societies of the present.

It is probably in this new way of understanding and doing archaeology that the most effective and long-lasting attack on both the discipline's claim to authority as a group (as McGuire correctly points out, the structure of the profession follows the guild model), and the legitimacy of its aspiration to be the only authorized agent to study and make sense of the past, can be found. As a matter of fact, one of the things indigenous peoples demand from the discipline is to stop having the monopoly of decision-making throughout the archaeological process. In this type of situation, the conflicts are played out and negotiated in different fields of action, and the arguments used by the parties involved cover a wide range that goes from the cultural to the political (and the economic). Yet, without a doubt, the most important, the most decisive sphere were the conflict is discussed, is the legal system. This is why it can be argued that the approval of a series of laws throughout the world, from the 1990s on, about repatriation and restitution of human remains and associated materials (of which the one known as NAGPRA, approved in 1990 in the United States, is paradigmatic), has had unique repercussions in the way in which the discipline is imagined and practiced, because it forces archaeologists to communicate, consult, and collaborate with indigenous living peoples.

As Joe Watkins has rightly pointed out, it is a pity that archaeologists had not themselves promoted this kind of democratic practice before the law forced them to do it, because it precluded the possibility that consultation and collaboration with indigenous subjects could be the product of

a conscious ethical decision on their part (Watkins 2000: xii). The fact is that thanks to this kind of legislation, archaeologists are not (in several countries), today, the only legitimate actors for the task of interpreting the past – that is, they are not the only agents that can decide on matters related to indigenous pasts. Nowadays, indigenous groups have the opportunity to be part of those processes of decision-making, which relativizes and undermines archaeologists' previously exclusive authority.

These indigenous struggles for obtaining the chance to be part of the interpretation, preservation, and study of their own past, are attempts at restituting some equilibrium in the face of the above mentioned differential of power that Sonya Atalay calls power imbalance, that kept indigenous peoples outside the processes that led to decisions regarding their own cultural heritage (Atalay 2011: 48). According to this author, those struggles against the existent power imbalance may end up benefitting other oppressed communities at a global scale (Atalay 2011: 48). The efforts made in that direction have taken diverse forms, one of which is the development of archaeological programs by some indigenous communities (for example, the Navajo, discussed in Watkins 2000: 93–103) who endeavor to study their own past without the help or intrusion of intermediaries. This is not the most common case, because the number of indigenous groups that do not have an archaeology program is much higher than the one of those who have one. More frequent is the case of individuals belonging to indigenous communities who decide to dedicate themselves to the profession in order to change it from within, so to speak (see a rather complete panorama of this growing group of people in the book edited by Nicholas). Last but not least, a modality that becomes more common with time: programs of collaborative archaeology in which individuals of different ethnic backgrounds undertake archaeological investigations in which indigenous values that were absent in mainstream practices are now present. The presence and importance of said values depend, in good part, on two undertakings: consultation and collaboration among different groups.

Some authors, like Nina Versaggi, opine that the kind of consultation required by the law, which is a one-time thing or an event, is not enough to reestablish some equilibrium in the distribution of power among the actors. On the contrary, in her view, consultation must be both continuous and meaningful; it must be a process instead of an event (Versaggi 2006: 30). For other authors, consultation, although a vital element in the whole process, is not enough because only collaboration leads to "praxis" – that is, to a series of conscious actions that intend to change the world (McGuire 2008: 8). For another author, Cara Lee Blume, the collaboration process differs from consultation in that the former means "to work together" (Blume 2006: 210). And according to the same author, the only way collaboration can happen is through the participation of indigenous communities in all the stages of the research process, which implies, for archaeologists, to share power, so that indigenous participants can be part of the instances when decisions are made (Blume 2006: 198). In this way, the new scenario contributes to fight the power imbalance that Atalay talks about and the power differential, if your prefer Said's parlance.

In sum, for at least a couple of decades, archaeologists' authority as the only legitimate agents for the interpretation of the past of the diverse communities that inhabited the planet, has been systematically questioned.

Although this is a situation that puts them in a less privileged position than in the past, it is arguably an opportunity to produce a better science, and a less biased, more democratic knowledge. This is why special attention should be paid to what Cristóbal Gnecco proposes as possible ways in which archaeology could recover some legitimacy in these times when the discipline is undergoing a certain degree of decolonization: to help in the processes of recovery of the local traditions and histories that it contributed to silence and erase in the (sometimes much too recent) past; to become public; to question its long association with the national narratives; and to abandon the academic ghetto to embrace and reach, at last, a wider variety of social sectors than it used to (Gnecco 2008: 30–1). What can be done, then, is to use the expert knowledges that have traditionally been at the service of the exclusion and subalternization of the West's others, to favor the

causes and projects defended and undertaken by the latter (Verdesio 2005: 142). This is in tune with what Funari says about the World Archaeological Congress (WAC): its objective is to promote an archaeology that seeks to liberate, instead of to exploit, the world (Funari 2006: 74).

Nona Avanesova

Vladimir I. Ionesov[1] and Armen Kasparov[2]
[1]Department of Theory and History of Culture, Samara State Academy of Culture and Arts, Samara, Russia
[2]Department of Archaeology, Samarkand State University, Samarkand, Uzbekistan

Basic Biographical Information

Nona A. Avanesova is a recognized expert in the field of the Paleo-Metal Age of the population of the Eurasian Steppe cultures and South of Uzbekistan. She is an authoritative researcher and

Nona Avanesova, Fig. 1

practicing field archaeologist, a professor at the Samarkand State University (Fig. 1).

In 1967 she graduated with honors from the History Faculty of Samarkand University. She was soon sent to Leningrad, where she was accepted as an intern at the State Hermitage. By this time she began her first publications and participation in scientific conferences.

She graduated from the graduate school in Leningrad, specializing in archaeology in the Department of Archeology of the Leningrad State University and in the Leningrad branch of the Institute of Archeology of the Academy of Sciences. Upon her return to Samarkand, she was accepted as assistant to the chair of archeology, where she currently works as a Professor.

In 1986 N. Avanesova became the head of the Department of Archeology of the History Faculty of Samarkand University. In 1999, at the invitation of the dean of the Humanities Faculty of the Higher School of the Sorbonne University, Nona Avanesova lectured on the problems of the Bronze Age of the steppe part of Eurasia. In 2016 she was awarded the honorary title of visiting professor of the Samara State Institute of Culture.

Major Accomplishments

The scientific heritage of Nona Avanesova includes the huge massive studies of historical and archaeological material on the Paleo-Metal epoch of Central Asia and cultures that combine the synthesis of agricultural and cattle-breeding traditions.

Her scientific research is connected with fieldwork and the excavations of archaeological monuments of the Stone and Bronze centuries in Kazakhstan, Tajikistan, and Southern Siberia. Under the leadership of Mikhail P. Gryaznov in 1979 in Leningrad, Avanesova defended her doctoral thesis. The theme of her scientific work is "The Problems of the History of Andronov Cultural Unity (on Metal Products)." The sphere of her professional interests includes many topics – the development of ancient crafts, cultural genesis, mythology, symbolic practices, funeral rite, intercultural communication, museum practice, and more.

In 1985, academician A.A. Askarov invited her to study the monuments of the Sapalli Culture of the South of Uzbekistan. Since then, the necropolis of the Bronze Age Buston VI has become the main object of archaeological research of N. Avanesova [1995, 1996, 1997, 2013a, 2016a, 2016b].

For three decades, unique materials were collected, and fundamentally new ways of illuminating the historical roots of the peoples of Central Asia and the ethno-cultural contacts of the ancient settled agricultural and cattle-breeding inhabitants of the Eurasian continent were proposed. N.A. Avanesova put forward a reasoned enough hypothesis that ritual sets of artifacts of the necropolis of Buston VI can be reconstructed as a specific figurative subject letter, which is based on the subjects of the Rigveda.

N.A. Avanesova discovered in the structure of the necropolis a series of specific structures

(boxes) for the cremation of the deceased. She studied this material thoroughly. Currently, throughout the territory of the Eurasian continent, these buildings are the oldest crematoria, dating from the end of the second millennium BC.

After the analysis of these materials, some issues of the cultural genesis of the Proto-Bactrian civilization were revised. In addition, significant additions and changes to the issue have been made, such as the formation of the oldest trade routes in the vast area of the Great Silk Road.

These and many other issues are reflected in more than 150 scientific works published by Nona A. Avanesova in Uzbekistan, Kazakhstan, Russia, Tajikistan, Germany, France, England, and the USA [Avanesova 1991, 1995, 1996a, 1997, 1998, 2013a, 2016a, b) and Avanesova and Ippolitova 2016]. She is the author of four textbooks and four monographs: "Culture of Steppe Cattle-Breeding Tribes of Bronze Age of Asian Part of USSR" (in Russian, 1991), "Sarazm Céramaques (Chalcolithique et Bronze Ancien)" (co-authors B. Lyonnet and A.Isakov). The last monograph "*Buston VI – the Necropolis of Fire-worshippers of Pre-Urban Bactria*", published in late 2013, provoking a wide interest among many foreign specialists, already in 2016 was translated into English [Avanesova 2016a].

For more than 30 years, Nona A. Avanesova has been the head of the Archaeological Museum-Laboratory at the Samarkand State University. The museum's holdings include about 60,000 exhibits in a wide chronological range – from the eras of Paleolithic to the Late Middle Ages. Nona A. Avanesova has many remarkable achievements.

Aviation Archaeology

Fiona Shanahan
Melbourne, VIC, Australia

Brief Definition of the Topic

Aviation Archaeology involves the investigation of material remains associated with the act of

flying. It encompasses aircraft and includes, but is not limited to aeroplanes, helicopters, hot air balloons, gliders, flying boats, antiaircraft installments, terminals, airbases, airfields, control towers, camps, and airstrips. The personal effects of people associated with aviation whether in a civilian or wartime environment also form part of the material culture of aviation archaeology. Examples may include airbase and aircraft construction and repair equipment, pilot-related resources, as well as materials associated with airbases, camps, control towers, and hangars.

Aviation sites have greatly transformed landscapes throughout the world, and yet the development and appreciation of aviation archaeology as an area of academic inquiry is only recent as it has been treated as a subset of historical archaeology and conflict archaeology. The relative neglect of aviation sites is due to a misconception that all material remains relating to aviation have been recorded in the archives and that therefore additional information cannot be obtained (McCarthy 2004: 82). The best example of this misunderstanding is the aeronautical engineering advances and alterations evident in World War II aircraft wrecks, which were not recorded in the archives. Investigations of archival materials related to aviation activities have brought to light the limited and often incomplete nature of information contained in reports (Shanahan 2014). There are repairs, modifications, and the construction of aviation structures and aircraft which do not feature in written records. The examples of reports having been lost or misplaced reinforce the necessity for contemporary archaeological investigations to complement the incomplete written record.

Misconceptions regarding the nature of aviation sites and materials are not the only challenge associated with the study of aviation archaeology. This subfield of archaeological inquiry is confronted with three major challenges. First is the issue of defining the site boundaries of aviation sites. This field of inquiry ranges from the investigation of terrestrial and maritime small, mobile sites such as aircraft wrecks as well as large, permanent terrestrial sites like control towers and hangars. Secondly, relic collectors and aviation enthusiasts often locate aviation sites before archaeologists. This leads to information loss and material damage when materials are taken off site or removed from their primary context on site. For this reason, aviation archaeologists have few intact sites from which to establish methodologies and comprehend site formation processes. Finally, heritage legislation worldwide regarding aviation sites is insufficient and often nonexistent. The lack of protection for sites allows relic collectors and enthusiasts to interfere with sites without guidelines. Often, the only protection offered to aviation sites is when aircraft wrecks are associated with human remains.

Archaeological work undertaken in Australia and the United Kingdom has generated positive improvements, understanding, and the development of aviation archaeology as a recognized subfield of archaeological inquiry. Jung and McCarthy (2001; 2004: 184), for example, have established site significance criteria and site report cards in Australia that will assist in archaeological fieldwork. Investigations regarding metals on aeroplanes in marine environments conducted by conservation staff at the Western Australia Museum have allowed World War II aircraft to be removed from rivers and ocean floors in Europe and placed under conservation management plans. In 2002 and 2003, English Heritage produced two guidance manuals relating to World War II aviation heritage sites, their management, and significance. Finally, the Australian Department of Sustainability, Environment, Water, Pollution, and Communities expanded the Australian National Shipwreck Database to include aircraft (Wilkinson 2012: 34). This development has led to discussions regarding the inclusion of aircraft in federal and state heritage legislation in Australia. Examples of such inclusions are evident in the 2011 Northern Territory *Heritage Act*. Similar legislation is currently being developed in the United Kingdom and throughout the Pacific.

As the field of aviation archaeology develops, so will archaeologists' understanding of site formation, conservation and management of aviation sites worldwide. These developments will reduce the severity of challenges associated with this sub-

field of inquiry and decrease misconceptions and neglect that impact on aviation archaeology today.

Avocational Archaeology

Donald Henson
York, UK
Institute of Archaeology, University College London, London, UK

Introduction and Definition

Finding a suitable term to describe people who do archaeology without being paid a salary, who do it mostly as a leisure pursuit, is not easy. Many terms have acquired emotional baggage through misuse over the years or have inadequate definition to be accurately used. Avocational is often used as the opposite of professional but is a term seldom used in the UK. We usually talk about the voluntary sector and of volunteers, although this can apply more widely to work placement students as well as people doing archaeology outside the professional sector. An older term is amateur archaeologists, although this has been used as a dismissive term by professionals as though being amateur were somehow less worthy or of lesser standard. It is often seen therefore as a politically incorrect term, the use of which involves an attitude of condemnation towards nonprofessional and therefore slipshod standards. The proper use of the word amateur simply means working for pleasure rather than financial gain. It is therefore entirely appropriate to use as a way of describing people who do archaeology without being paid a salary. Avocational is also a term that begs questions about assumptions and definitions. I will use all three terms interchangeably since the use of one term alone will become tedious through sheer repetition and some variation is needed for stylistic aesthetics.

Avocational archaeologists are people with a passion for the past as experienced through archaeology but have not chosen to follow a professional career in the subject. They are volunteers in their archaeology. Moreover, they are not content to watch archaeology from the sidelines. They

are not mere spectators. People who watch archaeology programs on television are not avocational archaeologists. Nor are people who visit heritage sites or stand behind barriers watching excavations in progress. Nor are people who attend lectures in archaeology. Avocational archaeologists are those who practice archaeology in whatever form during their spare time without personal income or profit.

One question immediately springs to mind as to how comparable these volunteer archaeologists are to professionals in their level of skills and contribution to the study and protection of the past. The role of education is to make sure that volunteers work to the same level as professionals and put into practice the appropriate disciplinary standards.

Where volunteers work within the context of professional organizations, perhaps on work placements as students or as volunteers carrying out agreed special tasks, then they will be trained and fully incorporated into professional levels of practice by their host organization. Where they work on their own as individuals or as part of local groups and societies, the issue of training and education becomes more important.

Historical Background

Archaeology began as an amateur pursuit. In the United Kingdom, most of the early archaeologists of the seventeenth, eighteenth, and nineteenth centuries were volunteers. Some of the great names in the history of archaeology had no employment as an archaeologist. Sir John Evans (1823–1908) was a paper manufacturer, while Sir John Lubbock, Lord Avebury (1834–1913), was a banker. It was in the nineteenth century from the 1840s to the 1870s that most of the county archaeological societies were created. The members of these societies were mostly middle-class professionals with the income and time to devote to archaeological study, such as doctors, clergymen, and lawyers. They carried out archaeological fieldwork and published the results of excavations and surveys. Some early volunteer archaeologists were active over long careers. John Mortimer, a corn merchant, excavated more than 300 barrows in Yorkshire from 1863 to 1900 to what was a very high standard for the nineteenth century.

Newer, more local archaeological societies were founded throughout the twentieth century, especially from the 1950s to the 1980s. The social makeup of their members was wider than in the nineteenth century but was still mostly educated middle class. However, the context of their activities was changing. The 1970s saw a great expansion in professional archaeology, in both universities and field units. The profession grew from around 200 people in 1960 to around 4500 in 2000 and around 6500 in 2010. With greater domination by professional archaeologists, the discipline began to systematize its practices and develop an idea of appropriate professional standards. A set of National Occupational Standards was drawn up by the then Institute of Field Archaeologists (founded in 1982 and now the Institute for Archaeologists) in 2002. Nevertheless, the professional sector is small in numbers compared with the amateur sector. A report by the Council for British Archaeology identified more than 200,000 people belonging to local voluntary societies and groups with an active interest in the historic environment (Thomas 2010).

The way that archaeology developed in the United Kingdom as an amateur discipline has meant that there is no legal sanction against anyone carrying out archaeological work, including excavation. There is no system of licensing of practicing archaeologists within England, Scotland, or Wales (although there is in Northern Ireland). Avocational archaeologists can therefore carry out archaeological investigations. The UK also has a vibrant metal-detecting sector who can also legally detect for finds and may be considered by some as part of the avocational sector (although views among archaeologists on this inclusion of detectorists as part of "the family" are sharply divided).

The avocational sector of archaeology has a long tradition of fieldwork and publication and can research parts of archaeology the modern professional sector seldom has time or resources for. Amateur archaeologists are not limited to working in opportunities provided by the

planning system, and are especially strong in being able to carry out research in rural areas, and have often pioneered new areas of research, such as the archaeology of industry, transport, or twentieth-century defenses.

Key Issues

Given that avocational archaeologists in Britain carry out fieldwork, one of the key issues is how to maintain adequate standards in archaeological fieldwork. Some archaeologists may have an instinctive distrust of amateurs. They are "not one of us" and have not been through the same education and training. However, many amateur archaeologists have been active in the field for decades and have levels of experience rarely matched in the professional sector. Some will also have university archaeology degrees, having not chosen to pursue a career in a poorly paid profession and found more lucrative jobs instead while keeping their interest alive as a leisure time pursuit.

What the voluntary sector needs is training in knowledge of archaeological artifacts and sites, the acquisition of methodological or technical archaeological skills. In part this can come from the previous generation of volunteers within their local societies. However, the main source of knowledge and skills has traditionally been university teaching through part-time courses aimed at the general public. The terms used to cover these courses have changed over the years from extramural provision to continuing education to lifelong learning. Whatever the term used, they involve university staff, postgraduates, or highly qualified professionals delivering evening and weekend courses through lectures and seminars and summer field schools based around excavation or field survey. Some of these field schools were long-term research projects such as that at Wharram Percy run by Maurice Beresford from 1950 to 1990 and the Shapwick project run by Professor Mick Aston from 1989 to 1999. One advantage of such courses was that the adult students could be taught by postgraduates at the cutting edge of academic research, and the postgraduates gained early experience at teaching which would be useful for an academic career.

Gradually, funding for these kinds of university courses came under increasing pressure. While some universities still manage to run a program of archaeology lifelong learning courses, many no longer do so. The pressures on these courses stem from an instrumentalist vision of education held by government which demands that in return for state funding, higher education must deliver tangible benefits for society. Such benefits are usually seen as financial and economic. Do courses help people find work? Do courses benefit the local or national economy? Archaeology belonged firmly within a tradition of liberal adult education: education as worthwhile for its own sake as humanizing the individual. It was clearly out of step with instrumentalist views about education. Government funding for adult education became diverted towards vocational training courses, and archaeology found itself left out in the cold. Only where there is strong managerial support for traditional education have liberal adult education courses survived, and such courses are expected to be as self-funding as possible.

Participation in such courses by mainstream academic staff and postgraduates was also under pressure due to the relentless drive for research excellence as almost the only measure of academic worth and funding in higher education. Excellence in teaching has long played second fiddle to research, and courses no longer compete on the academic CV at the same level as the peer-reviewed research paper in a prestigious journal. Now that the UK government has accepted that a measure of universities' impact outside academia on wider society should be a measure to take into account for receipt of funding, it may be that attitudes will change.

Since 1994, there has been funding for community-led heritage projects through the Heritage Lottery Fund, augmented by a separate Local Heritage Initiative funding from 2000 to 2006. As a result, there has been a renewed expansion of local heritage groups, many of which engage in archaeology. The funding has supported not only existing groups but also the

founding of new ones, often on an intensely local geographical base. This has meant an increasing demand for education and training in archaeology. In order to meet this demand, the profession has begun to employ people with the necessary skills in community outreach. In many cases, these new posts have been project funded, only rarely treated as part of the core function of the organization. What these community archaeologists can do is both train local people in archaeological skills and arrange access to professional equipment and specialist help. The old model of university-based support for amateur archaeology is being augmented, and in many areas replaced, by a partnership between professional archaeological organizations and local amateur societies.

International Perspectives

Great Britain (that is the United Kingdom less Northern Ireland) is somewhat out of step with the rest of Europe. Most other European countries operate a system of licensing, where only licensed (in practice only professional) archaeologists can carry out or supervise archaeological excavation. This is not the case in Great Britain. The continental position has been given prominence in the European Convention on the protection of the archaeological heritage (revised) as passed by the Council for Europe at Valletta in 1992 (known simply as the Valletta Convention), in which Article 3 (ii) states that each signatory will undertake:

> To ensure that excavations and other potentially destructive techniques are carried out only by qualified, specially authorised persons.

The signing of the convention by the UK government caused considerable alarm in sectors of British amateur archaeology. In practice, the interpretation of the convention is left to individual states, and the responsible bodies in the UK have no intention of enforcing a system of licensing or in restricting voluntary sector archaeology. Systems of protection through the scheduling of important sites, the role of archaeologists within the planning system, and the usually good relationships between local societies and professional organizations, along with the long record of high-quality fieldwork by many societies, are deemed enough to ensure that the archaeological resource is protected from inexperienced destruction.

Future Directions

Avocational archaeology in the United Kingdom seems to be in a secure position. Provision of education and training for amateur archaeologists is recognized as needed within the profession. Future trends in that provision may be towards a more systematized and nationally recognized framework instead of the varied and local responses currently in place.

Moves by the Institute for Archaeologists towards gaining the status of a chartered body, and therefore towards improving the status of archaeologists as chartered professionals in the same way as being doctors or engineers, could be seen as potentially closing off the discipline into chartered and unchartered sectors. It is important therefore that the IfA has within it a voluntary and community archaeology special interest group and that the IfA continues to be open to membership from both professional and amateur archaeologists. The IfA's annual conference is a major meeting point for the discipline where training in archaeology can occur. Importantly, the IfA also oversees the vocational Qualification in Archaeological Practice, based on the National Occupational Standards. This is an important avenue of training and education for the voluntary sector. Some have already taken advantage of this, although the costs of taking the qualification may be a deterrent for others. The qualification is based on best practice in archaeology, defined by the Institute for Archaeologists through their standards and guidance. The Council for British Archaeology, funded by English Heritage, has been leading a project, the Introduction to Standards and Guidance in

Archaeological Practice (ISGAP), to translate these into a form that is more user friendly and suitable for the voluntary sector across the whole United Kingdom. The introduction highlights best practice for voluntary groups and outlines standard procedures for carrying out archaeological research and investigation. The project's documents have recently been made available at http//:www.isgap.org.uk.

The Council for British Archaeology has been successful in attracting sponsorship to organize funded placements for community outreach officers to help train a new generation of archaeologists with the skills needed for supporting the voluntary sector. There are also a few postgraduate courses in archaeology in public engagement in archaeology helping to provide a future generation of professional archaeologists who are enthusiastic about supporting the voluntary sector.

While many people would not think of metal detectorists as avocational archaeologists, there is no doubt that they are part of the community of interest in the remains of the past and can be seen as part of the wider family that has archaeologists at its center. They produce data which adds to our archaeological knowledge. The Portable Antiquities Scheme in England and Wales does much to educate and train detectorists through its network of Community Liaison Officers. Detectorists also commonly enroll on traditional lifelong learning courses to increase their own knowledge of archaeology.

The future for avocational archaeology in Britain seems secure, so long as the funding is in place to make sure that amateur archaeologists of all kinds have access to the support they need for knowledge and skills from the professional sector. Archaeology in Great Britain is a partnership between professionals and amateurs, in which both are stronger that they would be alone.

Case Studies

The biennial British Archaeological Awards recognize excellence in various aspects of archaeology. One of the awards is the Pitt-Rivers Award for the best project by volunteers. There were two joint winners in 2012: the Norfolk Historic Buildings Group and the Washingborough Archaeology Group.

The Norfolk Historic Buildings Group produced a report on buildings within the village of Buckenham. They had a 5-year plan to survey the buildings, and as some of the members had previous experience of building recording, they were able to train the others on the necessary techniques. Heritage Lottery Funding allowed them to get dendrochronology dates for some of the houses and to publish their results. They produced the largest collection of vernacular houses to have been dated by dendrochronology in the county of Norfolk.

The Washingborough Archaeology Group was a founder member in 2001 of the Witham Valley Archaeological Research Committee. The group concentrated on intensive field walking and auger surveying under the rapidly eroding peat soils of the valley. This identified many archaeological sites and provided an accurate topographical map of the valley. The work was funded by other organizations which also provided surveying equipment in return for access to the results of their work. Specialist reports were produced by the group with some professional support.

The prestigious special award of the Graham Webster Laurels went to the Upper Nene Archaeological Society which has been excavating at Piddington Roman Villa for 27 years. Along the way, they have trained their own members and encouraged them to become specialists in various archaeological disciplines. The society raised their own funds to buy a redundant chapel and turn it into to a modern museum with a viewing area and rooms where students and local school children are given training.

The British Archaeological Awards also have another category, the IfA Award, for the best professional or professional/voluntary archaeological project that demonstrates a commitment to professional standards and ethics in archaeology. In 2012, this went to the Whiteleaf Hill Local Nature Reserve Project. This was a project initiated by community representatives with the help of Buckinghamshire County Council and Oxford Archaeology. The local community excavated, conserved, and interpreted the remains on

Whiteleaf Hill for future generations. The sites included a Neolithic barrow, a Bronze Age dyke and two supposed round barrows, First World War practice trenches, sunken trackways, and ancient and modern woodland. The project involved an emphasis on research and conservation but also integration of the historic and natural environment and an education program for local schools, all under strong community leadership.

A separate award, the Marsh Award for Community Archaeology, was held in 2011. The winner of this award was the Dartmoor Cairn Survey and Repair Project that started in 2005. This recognized the work of the Dartmoor Preservation Association (DPA) Conservation Team, Dartmoor National Park Authority (DNPA), and English Heritage in providing opportunities for volunteers to become involved in a professionally led project. Cairns that marked Bronze Age burials or territories were slowly being altered by people adding or removing stones. The project created opportunities for different groups such as scouts and other youth groups, businesses seeking team-building projects, and students requiring work experience to get involved. The quality of the work done was exceptionally high and depended on the close working partnership between the volunteers and the organizations involved.

Summary

Avocational archaeology, also described as voluntary or amateur archaeology, is a thriving part of the discipline in the Great Britain. Avocational archaeologists work without being paid and receive no personal financial benefit for their work. It has a long history of research and publication and continues to contribute to our understanding of the archaeological remains of all periods from prehistory to the modern world. Many amateur archaeologists have a great deal of field experience and high levels of archaeological skills. A key part of the voluntary sector's success lies in the education and training that amateurs receive from professional archaeologists based in universities, archaeological agencies, and field units. This support has traditionally been through university continuing education courses, although less so than previously due to changes in government funding. More recently, support is becoming more widely available through the new field of community archaeology where professional archaeologists support local societies and groups directly in the field. Much amateur activity is supported by funding from the Heritage Lottery Fund, which helps local groups buy in the professional expertise they may need for specialist tasks and helps with costs of publication of their findings. The profession is beginning to realize that the study of the past is too big a task for a small number of financially hard-pressed professionals. Together, professional and avocational archaeologists make a formidable research team.

B

Balkan-Atlı, Nur

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Nur Balkan-Atlı was born in 1953 in Aydın, Turkey After graduating from Robert College, she went to Paris and studied prehistory, anthropology, and ethnology at Sorbonne University. She received her M.A. and Ph.D. with a dissertation titled *The Neolithization of Anatolia* from the Sorbonne University in 1985. Atlı was assigned as a specialist to the Prehistory Department of İstanbul University in 1987 and was promoted to Assistant Professor in 1995 and then Professor in 2000.

Major Accomplishments

Nur Balkan Atlı's major field of study is the Paleolithic period of prehistoric archaeology and lithic technologies. Since 1995, she has mostly focused on the obsidian beds and working areas in the Cappadocia region in Turkey. After working in El Kown, Qdeir (Suriye), Cafer Höyük (Malatya), and Aşıklı Höyük (Aksaray) on excavations, she started an ongoing study through the Cappadocia Obsidian Research Project. She is connected to the French Institute of Anatolian Studies and is a researcher and a member of the monitoring committee.

Nur Balkan Atlı is also a foreign member of the French CNRS Archiorient Group, a local consultant of the European Commission INCO-MED Programme, and a member of the American Research Institute of Turkey and similar scientific institutions. She currently serves on the editorial board of journals including "Anatolia Antiqua" and "Paliorién." She has published the book *La Niolithisation de l'Anatolie* and numerous scientific articles.

Balme, Jane

Susan Arthure
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Jane Balme is an Australian archaeologist and leading researcher in the archaeology of Indigenous Australia. She is currently associate professor in archaeology at the School of Social Sciences, University of Western Australia.

Jane grew up mainly in Western Australia and was awarded her bachelor's degree in anthropology in 1979 from the University of Western Australia. As a graduate assistant in archaeology at the Western Australian Museum, she worked on cave sites in South West Australia. This sparked her interest in archaeology, and she enrolled in a PhD at the Australian National University in Canberra. Her PhD research on Pleistocene fishery on the Darling River in western New South Wales was awarded in 1990. She has worked as a consultant to the National Parks and Wildlife Service of New South Wales and as a lecturer in the Archaeology and Palaeoanthropology Department at the University of New England.

Jane has extensive research experience in the field, having worked on projects with Indigenous groups in northern and western New South Wales, southern Arnhem Land, the Kimberley region of North West Australia, and South West Australia. Most of her work has been on the archaeology of Indigenous Australia, and she has a particular interest in the Pleistocene period, the symbolic evidence of early art and adornment, and the role that symbolic differentiation between populations may have played in the colonization of the continent. She has also published on gender organization in hunter-gatherer societies, archaeology education, and public perceptions of archaeology.

Major Accomplishments

Jane Balme's research to date has been in three principal areas: social behavior and organization in early Australian Indigenous groups (e.g., Balme et al. 2009; Balme and O'Connor 2016), including Pleistocene Australia (e.g., Balme and Morse 2006; Balme and O'Connor 2014) and the nature of relationships between Indigenous groups and new European arrivals (e.g., Balme and O'Connor 2015); the development of gendered social organization, particularly in hunter-gatherer societies (e.g., Balme and Bowdler 2006; Balme and Bulbeck 2008; Balme and O'Connor 2016; Bowdler and Balme 2010); and archaeology as a discipline (e.g., Beck and Balme 2005).

She has held major research grants, usually in collaboration with other researchers. This has included funding under the Discovery Program of the Australian Research Council, as well as grants from the Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS), the Ian Potter Foundation, and the Australian Heritage Commission.

Jane has also contributed greatly to the Australian Archaeological Association (AAA),

the professional body for Australian archaeologists. She has held several positions in AAA over the years, including secretary and chair of the Australian National Committee for Archaeology Teaching and Learning. She is a consulting editor to *Australian Archaeology*, AAA's peer-reviewed journal.

Bam: Archaeological and Social Investigations After the Earthquake

Leila Papoli-Yazdi[1], Omran Garazhian[2] and Maryam Dezhamkhooy[3]

[1]Independent Researcher, Neyshabur, Iran

[2]Archaeology Department, Neishabour University, Tehran, Iran

[3]Heidelberg University, Heidelberg, Germany

Introduction

Bam is a desert city engaged in citrus and palm cultivation, whose residents dwelt in handmade mud-brick houses around an ancient citadel, which is a World Heritage Site (UNESCO 2005). It is located in the southern border of the Lut desert, in southeastern Iran. Despite this fringe location, it has traditionally served as a center for local trade. On December 26, 2003, the city was reduced to ruins by an earthquake in only 12 s. Approximately 40,000 people died, 30,000 were injured (Tahmasebi et al. 2005), and 100,000 people were made homeless (Mann 2005: 3). *Disaster ethnoarchaeology: Bam after the earthquake* was an ethnoarchaeological project aimed at recording this dramatic change (Dezhamkhooy and Papoli 2010; Papoli 2010; Papoli et al. 2011) (Fig. 1).

Key Issues/Current Debates/Future Directions/Examples

The project, which took place in five seasons from 2004 to 2007, was conducted by 40 archaeologists, 24 women and 16 men, Ph.D. candidates, and M.A. and B.A. students, all familiar with the local and cultural context and supported by the previous directors of the *Bam research foundation*. In the first four seasons, data gathering was based on an *ethnoarchaeological approach*. In the last season (2007), six ruined houses of different status and district were investigated by archaeological excavation. The main mission of the project was to discover the impact of the catastrophe

Bam: Archaeological and Social Investigations After the Earthquake, Fig. 1 Bam citadel after earthquake

on the intimate lives of the residents. In addition, the project also sought to understand from the strata how the settlement had previously been affected by Bam's inhospitable and unstable environment – drought, winds, and frequent earthquakes (see Mahalati 1988).

The lifeways of Bam and its immediate environment were surveyed in five categories: mortuary practices, material culture, population mobility, trade and market patterns, and domestic architecture. Data were gathered through observation and by questionnaires designed to record patterns of life before the earthquake. The recorded changes to everyday life were studied over the short, medium, and long term. Also recorded were accounts of the gradual return to normal conditions.

Recording damaged buildings was a key part of the archaeological inquiry. Bam's domestic architecture was first divided into three general architectural styles: modern (structures built on metal frames), semi-modern (plaster and clay mortar on metal frames), and traditional (made of mud-brick). Approximately 673 houses and 383 destroyed shops (Fig. 2) were evaluated during the first three seasons. These buildings were classified by their degree of damage: destruction of decorations, destruction of walls and roofs, or total destruction. The state of the buildings was compared with the socioeconomic status of the occupants, by district. For example, it was shown that most casualties occurred in the traditional type of housing, most vulnerable to earthquake and occupied by the least wealthy.

The excavations of the six houses (Fig. 3) showed that most of them had already been searched to discover the remains of the dead and to remove valuable materials. Most of the furniture remained. Divisions recorded within the houses led to information about the use of space and the implied spatial imperatives of gender, class, and wealth. People of higher status had more private spaces such as bedrooms or divided spaces based on gender and age, while the less wealthy had more common spaces, such as one bedroom for all the family. Differences in status were evident in other material culture too. The last moments of the six families were reconstructed from the disposition of the surviving cultural material.

There were interesting differences between the archaeological findings and the statements made on the questionnaires, no doubt through a reluctance to admit to activities of which authorities may have disapproved – such as sexual practices, drinking, or even watching some satellite channels. The earthquake and the subsequent

Bam: Archaeological and Social Investigations After the Earthquake, Fig. 2 Buildings for recording (shops)

Bam: Archaeological and Social Investigations After the Earthquake, Fig. 3 A store room of the Hafizabadi House under excavation Trench 1

archaeological excavations opened up private spaces such as bedrooms, revealing intimacies of everyday life, love letters, and personal entertainment tools.

Since the investigators were themselves indigenous, their relations with Bam residents developed naturally. But the feelings of the archaeologists were nevertheless strongly affected by the roles they were obliged to adopt. International and national aid initiatives rapidly altered the circumstances, the attitudes, and the decisions of residents. In addition, the changing policies of the Iranian government were determinant, eventually bringing the project to an end.

Bamiyan Buddhas

Ilona Bartsch
Department of Archaeology, Melbourne, Victoria, Australia

Introduction

The Bamiyan Buddhas were situated in the Hindu Kush mountains, in the central highlands of Afghanistan. They were the largest standing Buddhas in the world (Grun et al. 2004). The two main statues were built in 554 CE and 507 CE (Janowski 2011: 47) and were known in modern times as the West Grand Buddha and the East Grand Buddha. They were, respectively, 53 m and 38 m high (Grun et al. 2004: 178). The statues were carved into niches in the valley of Bamiyan, a center of Buddhist culture from the second century CE until the eighth century, and were part of a large complex of Buddhist temples, many of which still survive. The valley and the remains of the Buddhas are now a world heritage site (UNESCO 2003).

In March 2001, Afghanistan's effective government, the Taliban, destroyed the Bamiyan Buddhas in the face of huge international opposition and in defiance of international law (Francioni and Lenzerini 2003). Later discussion of the Buddhas centered on the stabilization of the larger site of Bamiyan and the possible reconstruction or restoration of the destroyed statues.

Definition

These two statues of the standing Buddha were located in the Bamiyan Valley, 200 km north-west of Kabul, in the Hindu Kush mountain ranges, 2500 m above sea level. The statues were carved directly into the cliff face. The geology of the cliffs consists of conglomerate and siltstone layers, with the siltstone being particularly vulnerable to the actions of water (Margottini 2004). The region experiences hot summers and very cold winters, and the freeze thaw cycle puts further pressure on the cliffs and the remains of the Buddhas.

The Western statue was the larger of the two. Before its destruction it was the largest standing Buddha in the world. It stood at 53 m high and was constructed between 591 and 644 AD. The Eastern statue was slightly smaller at 38 m and was built between 544 and 595 AD (Grun et al. 2004; Blánsdorf et al. 2009; Janowski 2011). A smaller statue of a seated Buddha was located between the Eastern and Western Great Buddhas, and it was destroyed as well.

In modern times the statues appeared to be without faces or arms. The lower legs of the larger Buddha were badly damaged in the seventeenth and eighteenth centuries by the moguls Shah Aurangzeb and Nadir Shah (Grun et al. 2004). The clearest ancient description of the statues is by Hsuan-Tsang, a Chinese monk who visited the site in 630 CE. He described the Buddhas as being gilded and decorated with precious stones. They also wore masks, and while the lack of facial features in modern times is often attributed to

vandalism, it is possible that this was an original feature designed to accommodate the wooden masks (Cotter 2001). The statues were originally constructed by carving their rough shape into the cliffs. The intricate gowns of the Buddhas were shaped by applying stucco to the rough carving, and the lower arms were made of wood (Knobloch 2002).

The statues were sculpted in the Gandharan style that blends Greco-Roman artistic traditions with Indian and Buddhist religious art (Grun et al. 2004). This suggests that the building of the statues was initiated at an earlier time than radiocarbon dates given above would suggest. Grun et al. (2004) state that the building of the Buddhas was instigated by the Kushan Dynasty, who ruled the area from the first to the third century CE. The Western, larger statue represents Vairocana, the "Light Shining throughout the Universe" Buddha, and the Eastern, smaller statue Shakyamuni, "The Awakened One of the Shakya Clan" (AIIS 2004). The artistic style represented here is believed to have inspired other sites in China such as Dunhuang.

The Buddhas were first recorded in Western literature by Alexander Burnes in 1832 (Grun et al. 2004). The first archaeological work at the site was undertaken by the Delegation Arche'ologique Francaise en Afghanistan in the 1920s and 1930s. The French recorded the site, began preservation work on some of the murals, and produced the first guide book to the Bamiyan Valley (Grun et al. 2004). A number of Japanese and American researchers continued working at Bamiyan in the late twentieth century, recording details, completing a photographic survey, and preserving the great statues. Most research at the site was put to a halt with the Soviet invasion in 1979.

Chiovenda (2014) records local Hazara myths about the statues. The Hazara name them *Salsal (Sang-Sal)* and *Shamama (Shamuma)* and assign gender to them, these names and genders are also recorded in the nineteenth-century ethnographic accounts of the statues from Moorcroft (1842) and Burns (1886). Some Hazara people identified the statues as representing the apical ancestors of their people; others recount a myth involving a wedding between the prince and princess of neighboring states within the valley who were turned to stone at the conclusion of the wedding ceremony (Chiovenda 2014).

Key Issues/Current Debates/Future Directions/Examples

In March 2001, the Taliban regime of Afghanistan, which controlled Bamiyan at the time, destroyed the Buddhas. The destruction of the Buddhas was part of a systematic destruction of all images in Afghanistan that were considered to be idolatrous. While the Buddhas were not the only victims of this wave of destruction, they were the most visible, and their destruction has come to symbolize the violence of the Taliban regime (Centlivres 2008; Janowski 2011).

It is possible that the Taliban's actions were more politically than religiously motivated. In 2001, Afghanistan had been at war for more than 20 years, and the Taliban had begun pushing for full control of the nation. In 1999, the Taliban made a commitment to protect Afghanistan's cultural heritage (ICOMOS 2001), but by 2001, the United Nations had imposed a number of sanctions on the country and had refused to acknowledge the Taliban as the government of Afghanistan, despite their effective control of the country. In this volatile political environment, the destruction of the Buddhas can be interpreted as an assertion of power on the part of the Taliban, rather than an action that was motivated solely by religious beliefs (Francioni and Lenzerini 2003).

The destruction of the Bamiyan Buddhas by the Taliban led to a reconsideration of the nature of war crimes and crimes against humanity. Francioni and Lenzerini (2003) found that the destruction of the Buddhas differs from the usual destruction of cultural heritage during wars because of the careful documentation of the destruction and the lack of a clear military objective. Instead, it can be viewed as act of defiance of the United Nations and of the international community (Francioni and Lenzerini 2003: 620). From this viewpoint, the destruction of the Bamiyan Buddhas can be viewed as a planned

action in a symbolic war between the Taliban and others.

In 2003, the United Nations inscribed the cultural landscape and archaeological remains of the Bamiyan Valley onto the World Heritage List (UNESCO 2003) under criteria i, ii, iii, iv, and vi. This area is currently listed as World Heritage in Danger. The inscription specifies the niches in which the Buddhas once stood, the sacred cave system, the remaining Buddhist art, and several other elements of the surrounding landscape as the main elements of the site (UNESCO 2003). Since the fall of the Taliban regime, the new Afghani government has attempted to preserve what remains of the Bamiyan Buddhas and their surrounds. The government has been working with UNESCO to stabilize the site, which is at risk due to natural process and the effects of the blasting that was done to destroy the Buddhas (Margottini 2004; Manhart 2004). Archaeological work has resumed at the site (Hammer 2010), and a systematic recording of the niches that remain has been undertaken, including computer and 3D modeling of the site (Grun et al. 2004).

When archaeologists visited the site in 2002, they discovered that the Buddhas had not been completely pulverized and that the remains were substantial and that reconstruction of the Buddhas was technically possible (Lawler 2002). Since this time, there has been debate over what should happen at the site. UNESCO does not support reconstruction, campaigning for a stabilization of the remaining aspects of the site and the preservation and display of the pieces of the Buddhas in a museum context. Many local people and members of the Afghani government support full reconstruction on economic grounds; they believe the reconstruction of the Buddhas will promote tourism and give the country a much needed economic boost (Gall 2003). This discussion is still ongoing in 2017 (Lluveras-Tenorio et al. 2017).

In 2013, a 3D laser light image of the Buddhas was projected in the niches in a special event. This illustrates one of the methods that has been suggested for interpretation of the site (IEEE Spectrum 2015). A 2009 report states that the geological and hydrological stabilization work being undertaken to preserve the niches in which the Buddhas once sat has mostly been completed, but that work is still ongoing in preserving the system of caves in the cliffs (Cripper and Margottini 2009).

The discussion over what to do with the remains of the Buddhas has led to a reassessment of the ethics of restoration and reconstruction in the academic literature (Gall 2003; Manhart 2004; Centlivres 2008; Janowski 2011). The UNESCO 10th expert working group released its recommendation for the Bamiyan site in 2011. They found that "in view of the available scientific data and estimated financial requirement, a total reconstruction of either of the Buddha sculptures cannot be considered at the present time" (UNESCO 2011). However, this does not rule out reconstruction at some point in the future. The remains of the Buddhas are currently stored for preservation, mostly at the foot of the niches in which they once stood (Lluveras-Tenorio et al. 2017).

Ban Chiang: Agriculture and Domestication

Charles F. W. Higham
Department of Anthropology and Archaeology, University of Otago, Dunedin, New Zealand

B

Basic Site Overview

Ban Chiang is a prehistoric settlement located in the northeastern part of the Khorat Plateau in Thailand. It came to prominence in the 1960s when elaborately decorated pottery vessels were found there. Excavations by Thai archaeologists then identified similar vessels in a cultural sequence that spanned the early Neolithic to the end of the Iron Age. The painted vessels were restricted to late Iron Age burials. These excavations coincided with claims based on the nearby site of Non Nok Tha that copper-based technology dated to the fourth millennium BCE which, if validated, would of necessity make Southeast Asia an independent center for the discovery of bronze casting.

Ban Chiang was soon to be almost entirely ransacked by looters, initially fed by visitors from a large, nearby American air base. Appreciating the potential significance of this site, the University of Pennsylvania Museum of Archaeology and Anthropology and the Thai Fine Arts Department appointed Chester Gorman and Pisit Charoenwongsa to direct rescue excavations. Two small areas were identified where looters had not yet penetrated, and fieldwork took place in 1974 and 1975. The cultural sequence of both areas, when combined, began with burials containing ceramic vessels decorated with incised and impressed patterns that typify the Southeast Asian early Neolithic. These lay under further human graves assigned to the Bronze Age, although copper-based mortuary offerings were very rare indeed. With the Iron Age, grave goods included bimetallic spears with an iron blade and socketed bronze haft, glass beads, deeply incised clay cylindrical rollers, and bones from domestic pigs and dogs.

Evidence of Early Agriculture

Radiocarbon determinations were initially derived from charcoal which came from two principal sources. The majority of samples were accumulated from fragments of charcoal recovered from grave fill, while a few came from in situ hearths. Gorman and Charoenwongsa (1976) reported that these confirmed the startlingly early date for the initial Bronze Age at 3600 BCE and further claimed that iron forging was under way between 1600 and 1200 BCE. This divided scholarly opinion down the middle, and Ban Chiang became a cause célèbre.

The untimely death of Chester Gorman in 1981 led to the appointment of Joyce White to analyze and publish the results of the 1974–1975 excavations. Appreciating the internal contradictions in the charcoal-based chronology, she began first to reinterpret the results and then, with the advent of AMS dating of very small organic samples, turned to a new dating program that involved extracting and dating the rice chaff that had been used in prehistory to temper mortuary pots.

This experimentally involved three different pretreatments. The two most relevant involved dating either the actual fragments of rice teased out of the pot matrix or the organic fraction of the entire

Ban Chiang: Agriculture and Domestication, Fig. 1 The radiocarbon dates of human and pig bones from Ban Chiang. *EP1* early Neolithic, *EP2* later Neolithic, *EP3* early Bronze Age, *EP4–5* later Bronze Age

crushed potsherd. A problem arose when dates obtained from both pretreatments from the same pot or burial presented offsets of centuries or even millennia. In the event, White has proposed a new chronology for Ban Chiang derived from six crushed potsherd determinations and one from rice phytoliths. These, she has suggested, indicate initial settlement of the site by Neolithic rice farmers in the third millennium BCE and the transition into the Bronze Age in 2000–1800 BCE (White 2008). This would mean that the inhabitants of Ban Chiang either themselves developed metallurgical capabilities or derived their knowledge from a source other than early Chinese states.

White and Hamilton (2009) have subsequently composed a model which identifies the source of the bronze casting tradition at Ban Chiang in the Seima-Turbino transcultural phenomenon of the Urals. Their proposed route for the passage of the necessary specialists covers at least 2500 km of Western China.

There are problems with this proposal. The first is the reliability of their radiocarbon chronology based on ceramic tempers. Although prima facie, this seems a valid technique, since the rice chaff is most unlikely to have inbuilt age, it is now recognized that clay itself can contain up to 15% of carbon, and this provides a spuriously early result. However, new methods for pretreating and dating bone, and then interpreting the results, provide a means of testing and refining their chronological framework. This has now been undertaken on the basis of the bones of those who lived at Ban Chiang and of the animals they interred with the dead (Higham et al. 2011a, b; 2015). The results harmonize with the chronologies obtained at other sites in Southeast Asia. The initial settlement of the site by Neolithic rice farmers took place in the sixteenth century BCE. This date for the initial settlement by farmers is several centuries later than in Northern Vietnam and Central Thailand. The transition to the Bronze Age occurred in the late eleventh century BCE (Fig. 1). As with other sites, iron forging began in the fifth century BCE.

With the expansion of fieldwork throughout mainland Southeast Asia in the last two decades, it is now possible to place Ban Chiang in its proper cultural perspective. It was one of many sites which was initially settled by rice farmers whose ultimate origin was the valley of the Yangtze River. This thrust south took place in the last few centuries of the third millennium and saw the incomers adapting and integrating with the indigenous hunter-gatherers. The problem with Ban Chiang as a source of information on the nature of rice agriculture is that no flotation was undertaken there during the excavations of 1974–1975 and no report on the site's stratigraphy, sequence, and any plant remains has been published.

The new Neolithic communities maintained exchange contacts with the rapidly developing states of the Yangtze, which brought jades and bronzes into Lingnan and Northern Vietnam, in exchange for cowries, turtle shell, and probably other desirable items such as kingfisher feathers. This exchange network probably involved the movement of specialist bronze casters south, for by the eleventh century, copper-based axes,

Ban Chiang: Agriculture and Domestication, Fig. 2 Bronze mortuary offerings like these bangles were very rare at Ban Chiang

Ban Chiang: Agriculture and Domestication, Fig. 3 One of the few Iron Age-painted pots recovered during the 1975 excavation at Ban Chiang

chisels, bells, awls, bangles, socketed spears, and anklets formed the base repertoire of the Southeast Asian Bronze Age (Fig. 2). At some highly strategic sites, such as Ban Non Wat, this stimulated the rapid growth of aggrandizer groups interred with great wealth in princely graves. But at more remote locations such as Ban Chiang, the Bronze Age graves were poor. Iron was probably introduced into Southeast Asia through the development of a major maritime trade artery linking the region with both India and China. Again, some Iron Age sites, such as Prohear in Cambodia, were exceptionally wealthy in terms of exotic bronze drums and golden ornaments. Ban Chiang, however, being remote from the main trade links, was still poor save for its remarkable red on buff-painted pottery vessels (Fig. 3).

Ban Non Wat, Archaeology of

Charles F. W. Higham
Department of Anthropology and Archaeology, University of Otago, Dunedin, New Zealand

Introduction

Ban Non Wat is one of the many moated prehistoric sites that concentrate in the basin of the Mun River in Northeast Thailand (Higham and Kijngam 2009, 2011, 2012a, b; Higham 2011a, b; Higham et al. 2011). It is a key site for

understanding the later prehistory of Southeast Asia for three principal reasons. A large area has been excavated over ten seasons. It has revealed a long and continuous sequence of occupation, and it has been dated on the basis of 76 radiocarbon determinations that have been subjected to Bayesian analysis.

Definition

This site is unique in Southeast Asia for the clarity and length of its prehistoric cultural sequence and the size of the analyzed material. There are 12 phases that begin with hunter-gatherers, followed by 2 Neolithic, 6 Bronze Age, and 3 stages of Iron Age occupation, each associated with human burials.

Key Issues

There are two key issues that dominate the interpretation and wider relevance of Ban Non Wat. The first is the application of AMS radiocarbon dating and Bayesian statistics to provide a valid chronological framework, and the second is to illuminate social change over 2000 years of continuous occupation that led ultimately to the formation of early states.

Current Debates

This site has contributed new and relevant information that tests alternative models on prehistoric cultural developments in Southeast Asia: the relationships between intrusive Neolithic rice farmers, the timing of the initial Bronze Age, the impact of copper-base metallurgy on social organization, and the social changes that took place with the adoption of iron technology.

The area excavated concentrates in the middle of this circular site, which has a maximum diameter of 320 m, with ten smaller excavation squares distributed in a linear fashion between the moats. The moats and banks that ring Ban Non Wat have also been excavated and dated. One of the problems that has hampered our interpretation of Southeast Asian prehistory has been the small areas excavated relative to the size of individual sites. By opening a large area, we have identified spatial patterns of activity on an unprecedented scale.

The sequence begins with occupation by hunter-gatherers, one radiocarbon determination on a shell midden falling in the sixteenth millennium BCE. However, the first of 12 fully documented cultural phases began in the early second millennium BCE, when the site was employed as a cemetery for a series of flexed burials that in all probability represent people of the local hunter-gatherer tradition. These would have found a richly endowed habitat, offering plentiful resources including fish, shellfish, and a wide variety of animals that included at least four species of deer, pigs, and wild cattle.

This phase partially overlaps the initial settlement by rice farmers, whose ultimate origin lies in the Yangtze Valley. They are represented at Ban Non Wat by their occupation middens and a cemetery, the radiocarbon determinations showing that they arrived in the seventeenth century BCE. The dead were interred with elaborate mortuary rituals. A man and a woman were found in a seated position within large, lidded pottery vessels notable for their elaborate incised, impressed, and painted designs. Two individuals were buried with cowrie shell ornaments, indicating long-distance exchange with coastal groups. Other offerings included pig bones, shellfish, and bivalve shells thought to have had ritual significance. Infants were interred in lidded pots identical in form to those used for adults but naturally smaller.

This first Neolithic phase was followed by a second, dated between about 1250 and 1050 BCE. There was a decline in the quality of the now virtually undecorated pottery vessels placed with the dead and generally a poverty of other mortuary offerings. However, this was prelude to a dramatic change in the mid-eleventh century BCE, when the initial Bronze Age phase at the site saw the dead interred in deep graves, within wooden coffins associated not only with copper-base socketed axes but also up to 15 finely fashioned

Ban Non Wat, Archaeology of, Fig. 1 Bronze Age burials

pottery vessels and a rich array of shell jewelry. Bronze Age 1 occupation gave way in the tenth century to arguably the most significant of all phases of occupation, for Bronze Age 2 witnessed a veritable starburst of social display in what can legitimately be described as princely burials (Fig. 1). This degree of wealth, unprecedented in the Bronze Age of Southeast Asia, saw men, women, and infants interred in very large graves, associated with up to 80 superbly painted mortuary vessels in many forms. Again, copper-base axes were placed with the dead, including some infants, as well as awls, chisels, anklets, and bells. There was a profusion of exotic marine shell jewelry including beads, earrings, and bangles, as well as marble bangles and earrings. The dead were also interred with fish and pig remains that strongly suggest that mortuary feasting took place at the time of burial.

Such feasting is a means whereby social aggrandizers can leverage their status through public demonstrations of hospitality and wealth. For at least eight generations, according to the radiocarbon chronology, this wealthy lineage retained its high status, while contemporary graves elsewhere on the site, and in a nearby settlement, were markedly poorer.

Part way through the third phase of the Bronze Age, in the ninth century BCE, this degree of wealth sharply declined. Although some individuals were still buried with multiple exotic ornaments, the majority were markedly poorer, with only a handful of pottery vessels and a few shell ornaments being associated. Now the dead were buried in cemeteries laid out in row, with many graves disposed head to toe in columns. One grave stands out. It was the burial of a young man accompanied by 29 clay molds for casting bronze socketed axes and bangles. The latter were cast in a manner not hitherto documented in Southeast Asia. A series of molds were set in place like books on a shelf, and the molten metal was then cast into them simultaneously. This is a form of mass production, but curiously, no bangles were found in any of the contemporary graves.

The sixth and final Bronze Age phase is dated from the seventh to the early fifth centuries BCE and saw some modifications to the ceramic forms while retaining the basic repertoire for decoration. Again, the dead were interred with modest offerings when compared with the initial phases of the Bronze Age. Now, however, many were accompanied by spindle whorls and lumps of clay. The former were used to manufacture the filaments prior to weaving, and the latter may be used as a dye or a mordant. It seems that the community in question was beginning to specialize in fabric production.

This continued seamlessly into the early Iron Age. Four Iron Age phases have been identified in the upper Mun Valley, and at Ban Non Wat, we can trace a seamless transition from the late Bronze Age to the earliest Iron Age as the cemetery expanded over time in an easterly direction. Thus, we can identify the point in this sequence where the first iron artifacts were placed with the dead and date it to the second half of the fifth

century BCE. This is the first time that this has been done in Southeast Asia. It is most significant that very rare beads and other ornaments of agate, carnelian, and glass were also found with the first people buried with iron. These forms of ornamentation are known to have been stimulated by exchange contact across the Bay of Bengal into India, and their conjunction at Ban Non Wat suggests that they came together, as a package, into the interior of Southeast Asia.

The first items to be forged from iron include large socketed spears, hoes, points, and bangles. There are also kits of small tools, such as knives and awls. The early Iron Age also saw a notable increase in the number of bronzes found, these taking the form of anklets, rings, and bangles on occasion cast using the lost wax method. Lead and tin items were also found, albeit rarely. During this earliest of the four Iron Age phases, many pots were placed with the dead, and these often contained complete fish skeletons. Pigs, cattle, and water buffalo limbs were also found in human graves, suggesting that feasting was a feature of this period.

A vital feature of Ban Non Wat, and many other Mun Valley Iron Age settlements, is that they were surrounded by multiple banks and moats. These are considerable engineering works that have for long been enigmatic. However, we excavated long trenches across them at several sites and identified not only the profile of the moats but the date of the encircling banks. It seems that the moats had a flat base, the banks being formed by heaping up the accumulated surface soil. The relevant radiocarbon determinations indicate construction in the third and fourth phases of the Iron Age, dating from about CE 200 to 600. The moats were fed by the rivers that then flowed past each settlement and could have been controlled to maintain a constant supply of water. Their actual purpose is not known, but they were probably multifunctional. Defense is one probability; we know that conflict was by now prevalent. The food offerings in Iron Age graves also remind us that wherever there is water in this region, there are also fish. There is also the possibility that the moats were an expression of the social standing of those who conceived them, for the later Iron Age was a period when immensely rich individuals were interred at the site of Noen U-Loke, only 1.8 km from Ban Non Wat. However, new information gained from the water flotation supports a new interpretation. During the Bronze and early Iron Ages at this site, the seeds of weed plants that invade rice fields were predominantly adapted to dryland farming. During the later Iron Age, we find a transition into plants that prefer wet conditions. This change occurred at the same time as moat construction, a sharp fall in the strength of the monsoon that brought a much drier climate, and the forging of iron ploughshares and sickles (Wohlfarth et al. 2016). The dead were now interred in graves filled with rice, and some individuals were accompanied by very rich mortuary offerings. These simultaneous changes are seen as the reflection of an agricultural revolution that saw rice being cultivated in irrigated rice fields that involved ploughing with the strength of domestic water buffaloes.

The terminal Iron Age in the upper Mun Valley overlaps the period known in Southeast Asia as Chenla, when the first inscriptions were composed. From these, we can read of chiefs, known as *pon*, who exercised authority over water reservoirs and whose communities included weavers, rice farmers, and herdsmen. It was from this social matrix that the civilization of Angkor was generated (Higham 2014). Thus, at Ban Non Wat, we can trace the entire course of prehistory from hunter-gatherers through the Neolithic, Bronze, and Iron Age to the origins of civilization.

Future Directions

The next stage in archaeological research in the Mun Valley of Northeast Thailand is to excavate further moated sites to provide comparative information on the course of prehistoric social change. This needs to identify further evidence for the presence of hunter-gatherers and their interactions with early rice farmers. The presence of a rich

Bronze Age elite at Ban Non Wat will come into sharper focus if similar groups can be found at other sites in the region. An elite can only be properly defined if contemporary poor lineages can be identified. These Iron Age sites are so large that their internal structure needs to be investigated. Thus, excavations at Non Ban Jak, a moated mound near Ban Non Wat, have revealed a residential quarter for the first time, with a lane separating rooms belonging to two different houses.

Ban Non Wat: Agriculture and Domestication

Charles F. W. Higham
Department of Anthropology and Archaeology, University of Otago, Dunedin, New Zealand

Basic Site Overview

Ban Non Wat is a large prehistoric site located in the upper Mun Valley of Northeast Thailand surrounded by a double set of moats and banks. Like the concentration of similar sites in this region, it sits upon a major route linking Central Thailand with the Khorat Plateau and beyond to the Mekong River and has immediate access to a vital resource, salt. Excavations began in 2003 and continued until 2010. An unprecedented large area has been uncovered, and few sites if any in Southeast Asia are as well documented.

Evidence of Early Agriculture

The cultural sequence is divided into 12 phases. These began with occupation by hunter-gatherers, who interred the dead in a tightly flexed position. A probable shell midden has provided a radiocarbon determination in the 16th millennium BCE, but the burials belong to the second millennium BCE. This was followed by two phases of Neolithic burials, six Bronze Age, and three Iron Age phases, all represented by human burials. This sequence has been dated on the basis of 75 determinations, some taken from in situ charcoal from hearths and others from the freshwater shellfish regularly placed as mortuary offerings with the dead. The Bayesian analysis of these dates shows that the initial Neolithic settlement began in the mid seventeenth century BCE. The transition from the late Neolithic to the Bronze Age took place in the late eleventh century BCE, while the Iron Age began in the second half of the fifth century BCE (Higham and Higham 2009).

For the first time in Southeast Asia, it has therefore been possible to assess the nature and pace of cultural change over a period of over two millennia in the context of a secure chronological framework. The initial settlement by Neolithic farmers saw that the inhabitants share the cemetery with those who chose to inter the dead in a flexed position. Such interaction between intrusive rice farmers and indigenous hunter-gatherers has become increasingly recognized in other Southeast Asian sites. Evidence for agriculture comes from the remains of rice in middens and a burial, while the dog, pig, and cattle bones come from domestic stock. The Neolithic inhabitants interred their dead either in an extended and supine position or within lidded mortuary vessels. The latter involved both adults and infants (Fig. 1). Pottery vessels were elaborately decorated with incised, impressed, and painted designs of considerable sophistication that are paralleled in other Neolithic sites from Central Thailand to Vietnam and north into China. Other grave goods include exotic cowrie shells, shell beads, bivalve shells, and pig bones (Higham and Kijngam 2011). The middens contain a wide variety of bones from hunted animals, fish, and shellfish. It was clearly an environment that provided an abundance of food.

Ban Non Wat: Agriculture and Domestication, Fig. 1 Burial 28 dates to the early Neolithic at Ban Non Wat and contained a man in a seated position within a large, lidded ceramic vessel decorated with incised and impressed patterns and painted designs

The transition into the Bronze Age is documented on the basis of seven graves that contain adults, infants, and children (Higham 2011a; Higham and Kijngam 2012). All reveal a sharp increase in the elaboration of mortuary rituals and the quantity of offerings placed with the deceased. Thus, where a couple of pots might be found with late Neolithic individuals, with Bronze Age 1, this rose to as many as 17. Socketed copper axes were a regular finding in these burials, as were shell beads and pig bones. This initial Bronze Age phase lasted perhaps no more than two generations before Bronze Age 2, when mortuary wealth rose to such a degree of wealth that we can describe the burials as princely (Fig. 2). Again, copper-based axes were regularly encountered, even with infants, as well as chisels, awls, and bells. The dead wore unparalleled quantities of exotic shell and marble ornaments, particularly bangles, beads, and earrings. Over 80 fine ceramic vessels were found, in many and varied forms, some bearing sophisticated painted designs (Fig. 3). A singular feature of these burials is that some men and women were partially exhumed and then the bones were replaced in a carefully placed heap within the grave. This might have been undertaken so that distinguished ancestors were incorporated within social rituals. There is little doubt that during this phase, Ban Non Wat harbored an elite social group that had secured preferential, perhaps restricted, access to exotic valuables that included copper, shell, and marble. The phase lasted from about 1000 to 850 BCE.

The ensuing phase saw a continuation of very wealthy graves, incorporating tens of thousands of shell beads, multiple shell bangles, and several bronzes. However, with phase 3B, the mortuary wealth fell sharply although the basic protocols associated with interring the dead continued: the same orientation, placement of pottery vessels, and creation of rows of graves. This relative poverty continued into Bronze Age 4, when graves covered the excavated area and were placed not only in rows but also head to toe. Bronzes were now very rare indeed, although one burial contained a bronze founder, a man accompanied by multiple molds for

Ban Non Wat: Agriculture and Domestication, Fig. 2 Burial 197 was one of the richest graves of the early Bronze Age at Ban Non Wat. The man was interred with several copper implements, richly decorated pots, and exotic shell bangles

casting bangles and two bivalve molds for axes. The final Bronze Age witnessed new forms of ceramic vessel, several containing complete fish skeletons as food offerings, as well as spindle whorls and clay that may well have been used to dye cloth.

Iron Age burials formed a seamless continuation from the late Bronze Age with virtually identical pottery vessels but also the first iron in the form of spears, knives, tool kits, and bangles. Three spears had iron blades and cast on bronze hilts. The first glass, carnelian, and agate ornaments were also found (Higham 2011b).

The excavation of a series of squares lineally across the site has shown how the settlement area progressively expanded over time. During the Iron Age, the floor of an area that had been used to impound domestic cattle and water buffalo was identified on the western edge of the site, and complex water control features on the eastern edge were in place as, toward the end of the Iron Age, the moats and banks round the site were constructed. In late Iron Age burials, there was a proliferation of glass ornaments in graves, along with more carnelian, agate, gold, and bronzes that reflect social change heralding the imminent development in the region of early states from the fifth to sixth centuries CE.

Ban Non Wat: Agriculture and Domestication, Fig. 3 Some of the mortuary vessels placed with the dead at Ban Non Wat were decorated with fine-painted designs (Reconstructed illustrations by Dr. Warrachai Wiriyaromp)

Bananas: Origins and Development

Edmond De Langhe
Laboratory of Tropical Crop Improvement, Katholieke Universiteit Leuven, Leuven, Belgium

Basic Species Information

A Multipurpose Crop

Bananas (*Musa spp.*) are a key domesticate of subsistence farmers across the wet tropics and subtropics. Although they are one of the most important commercial crops in the world, about 85% of banana production is for local food consumption.

The wild banana plant, which does not produce edible fruit, is still used for many other purposes within the primary center of banana diversity or natural range. Among remote societies of South and Southeast Asia, these uses include leaves for roof thatching, flower bracts as legume, leaf sheaths for fibers, and several parts of the plant for medicinal purposes (Kennedy 2009). These practices are likely to have a very long history and would have been crucial to the generation of cultivated banana varieties (cultivars).

Recent genetic, archaeological, and linguistic findings have substantiated this assumption (Perrier et al. 2011). These multidisciplinary studies have enabled the first reconstruction of the entire history of banana domestication and dispersal, from wild species to the current vast array of edible banana varieties.

The Key Role of Human Intervention

Banana plants are among the largest herbs in the world, and some specimens can reach 10 m height. As herbs, they propagate by means of seeds and side-shoots, called suckers. The cultivars are mostly sterile, with seedless fruits and very limited pollen production. Artificial propagation is vegetative (clonal) whereby suckers are collected and replanted. As a consequence, the presence of banana plants beyond the primary diversity center can only be due to human intervention, usually cultivation.

The planted suckers need about 1 year for fruiting and bunch harvest. Repeated vegetative propagation yields many cultivars with similar genetic composition. Thus, the plants are genetic markers of the people that introduced them originally to a region.

Botanical Background: Groups and Subgroups

The monocotyledon Musaceae family includes the Asian and African genus *Ensete*, the genetically proximal Asian *Musella* genus, and the East Asian genus *Musa*, which is divided into sections with 22 (Eumusa, Rhodochlamys) and 20 chromosomes (Australimusa, Callimusa). Almost all the cultivars belong to the Eumusa section and are diploid or triploid hybrids from *Musa acuminata*

(A-genome) alone or from hybridization with *Musa balbisiana* (B-genome) (De Langhe and de Maret 1999). Wild AA grow naturally within the humid-warm tropics part of the diversity center – from India to New Guinea – while wild BB are mostly confined to the drier periphery to the north, from NE India, over monsoonal Southeast Asia, to the Philippines.

Current cultivars are classified into groups according to the respective genome origins: edAA (for edible AA compared to the wild AA), AAA, AB, AAB, and ABB. In this classification, A and B indicate the genomes of the parental wild species. The existence of edBB and of BBB has still not been firmly established.

A cultivar group of minor significance, including Fe'i bananas, is confined to the Pacific region and is derived from Australimusa species (Kennedy 2008). It is not discussed further in this entry.

Only a modest minority of the about 600 cultivars have been strictly reproduced clonally. Many cultivars are the product of somatic mutations, slight genetic and/or epigenetic changes causing modest differentiation in features such as size, plant color, fruit form, and bunch structure. Within each group, the resulting sets of cultivars are called subgroups. They are quite distinct from each other. It is estimated that some subgroups, such as the AAB Plantains in Africa or the AAB Plantains in the Pacific, may contain up to 100 cultivars, all of them probably being mutants from one or a few original clones. Since somatic mutation is a relatively rare process, these considerable subgroups would suggest vegetative propagation over many centuries or millennia since the time of introduction to the respective regions.

Timing and Tracking Domestication

Stepwise Domestication of the Banana

Genetic research has shown that edAA were the original cultivars, from which all the triploid varieties and a few AB cultivars derived by various crossings. The evolution from wild to edible AA involved seed suppression and progressive parthenocarpy development. It is assumed, but not yet firmly demonstrated, that the latter evolution has been caused by century-long cloning. The development of partial to complete sterility, however, calls for the classical explanation that these edAA are in fact hybrids between wildAA parents of significantly different genetic composition, as is the common case with interspecific hybrids. Indeed, the species *M. acuminata* displays a quite pronounced morphological variation all over the *Musa* primary diversity center, with the variants confined to restricted areas. They have therefore been called "subspecies," and at least eight wild AA ssp. are recognized. Research with mtDNA and cpDNA markers has eventually demonstrated that edAA are inter-subspecific hybrids in various combinations, which explains the diversity in current AA cultivars (Perrier et al. 2011).

The pattern of banana domestication implies that plants from region-specific wildAA subspecies were moved between regions by human populations, for the natural hybridizations to become possible. Archaeological and linguistic investigation has revealed that such movements would have happened in the area of New Guinea and Eastern Indonesia even before the arrival of Austronesian-speaking peoples, perhaps around 4,000–3,500 years ago (Donohue and Denham 2009).

Triploidy Formation

Partially sterile AA cultivars can produce viable diploid gametes. If these are fertilized by haploid pollen, triploid bananas can be formed. Human interaction would have brought different cultivars into contact with other edAA as well as with wild AA subspecies and even the BB species. The addition of A or B genomes to these AA cultivars produced the large range in AAA, AAB, and ABB subgroups.

Because triploid bananas are more vigorous and robust than diploid ones, they largely dominate in all regions where the crop has been introduced. The ABB are typical for the drier tropics, while AAA, AAB, and the few AB thrive best in the humid tropics.

The current distribution of traditionally grown cultivars is rather complex, with more or less

characteristic sets in different regions of the tropics. For example, the AAB African Plantains are the only subgroup found in the lowlands of West and Central Africa, while an altitude-preferring AAA subgroup is typical for East Africa. The two subgroups probably have different histories, with different people responsible for their introductions at different times. On the other hand, the AAB Pacific Plantains are the only Eumusa traditionally grown in the Pacific islands to Hawa ii, which strongly indicates that their distribution is linked to the colonization of the Pacific by Austronesian-speaking ancestors.

The Need for Multidisciplinary Research

Banana plants do not contain wood, and the lack of seeds and pollen in the cultivars leaves phytoliths and starch grains as the most common vestiges of their existence in the past, which explains the difficulty in tracking their archaeological visibility (see Denham et al. 2009). The center of diversity poses the additional problem of distinguishing the phytoliths of wild bananas from those of cultivars, except for the metric distinction between edAA and AAA (Vrydaghs et al. 2009).

Circumstantial archaeobotanic evidence of domestication has only been found thus far. It has been demonstrated that *Musa* phytoliths found during the excavations in Kuk (New Guinea), dating to 7,000–6,400 cal BP, belonged to plants that were managed by humans (Denham et al. 2003). On the other hand, phytoliths found in West Africa in pits radiocarbon-dated to c. 2,500 cal BP do not belong to wild *Musa*, since they are beyond the natural range of *Musa* spp.; they, therefore, indicate introduction of the AAB Plantain under cultivation by that time (Mbida et al. 2001).

The above-explained example of AAB African and Pacific Plantains and altitude-preferring AAA shows how the complex geographical distribution pattern of subgroup presence can be a helpful historical marker of different human populations (see Perrier et al. 2011). Within this historical framework, linguistic research proves to be remarkably productive. Traditional generic names for crops are highly conservative within a language family, and analysis of their reflexes can provide the tracks for the presence of the corresponding people. A striking example is the evolution of the generic term ∗qaRutay, still used among the Aeta people in the Philippines, but of which an elucidated sequence of reflexes over Indonesia and Asia seems to mirror the movement of cultivated bananas from Eastern Indonesia to India (Donohue and Denham 2009). It is tempting to suppose that analogous sequences of subgroup generic names and their reflexes could shed light on many details of this human intervention.

Ranuccio Bianchi Bandinelli, Fig. 1 Ranuccio Bianchi Bandinelli

Ranuccio Bianchi Bandinelli

Dario J. M. Cavallo
Department of Historical Studies, University of Turin, School of Humanities, Turin, Italy

Basic Biographical Information

Ranuccio Bianchi Bandinelli was an Italian archaeologist, art historian, and politician (Fig. 1). He was born in Siena on the 19th of February 1900; his father, Mario Bianchi Bandinelli Paparoni, came from a noble family of Siena; and his mother, Margarete Ottilia von Korn Rudelsdorf, belonged to a noble family from the Lower Silesia. Unfortunately his mother died prematurely in 1905 when Bianchi Bandinelli was only 5 years old.

Bianchi Bandinelli was initially homeschooled by Rosa Arbesser, his grandmother from his mother's side, originally from Wien. He started to go to the public school in 1915, at the classical gymnasium F. Guicciardini in Siena (nowadays called E.S. Piccolomini), but shortly after he was interned because of the First World War. He started the military service in 1917 and attended the Academia of Turin for a year and a half only since he didn't want to become an official.

In 1918 he began to study archaeology at the University of Rome, and 5 years later he achieved his degree with a thesis about the Etruscan city of Chiusi. His thesis was then published in the series *Monumenti Antichi dei Lincei*.

In 1924 he got married to Maria Garrone and they had two daughters: Marta was born on the same year, 1924, and Sandra 4 years later.

Initially, Bianchi Bandinelli was uncertain about his career; he had to choose between taking care of the family's business while keeping archaeology as a secondary activity or making it his primary occupation.

He finally decided to focus on archaeology, and after teaching at the gymnasium in Siena, he became the professor of archaeology and history of Greek and Roman art in Cagliari in 1930. In the same year, his father passed away, and Bianchi

Bandinelli decided to sell *Villa il Pavone*, the family's house.

From 1930 to 1931, he taught in Groninga, in the Netherlands, while from 1934 to 1938, he was a professor at the University of Pisa. Later on he worked at the University of Florence (1939–1943) from which he had to resign during the Republic of Salò. Shortly after, he was taken hostage by the fascists and in 1944 he decided to become a member of the PCI (Italian Communist Party), in November 1944 he could go back to his position in Florence.

Once the war ended, he was appointed General Director of Antiques and Fine Arts with the task of coordinating the activities of restoration of monuments that had been damaged by the bombing; it was also his intention to start a project to retrieve and protect stolen works of art. Bianchi Bandinelli resigned from this position in June 1947, mainly because of political impediments to his work. At that point he decided to start teaching again first in Cagliari (1947–1950), then in Florence (1950–1957), and finally in Rome (1957–1964).

He stopped working as a professor in November 1964 frustrated by the conditions of Italian universities at that time. He continued to promote his way of thinking by supporting young students and publishing various papers to maintain alive his engagement against the carelessness of the public administrations toward the degradation of the artistic heritage.

Ranuccio Bianchi Bandinelli died in Rome on the 17th of January 1975.

Major Accomplishments

Bianchi Bandinelli conducted a life rich in intense cultural and political activities; he promoted numerous initiatives and published several important books that are still recommended as textbooks to Italian university students.

In 1926, after publishing his thesis, Bianchi Bandinelli worked for a little while at the Archaeological Museum in Florence where he was in charge of the Etruscan artifacts. On the same year, he submitted a project in order to create an archaeological map of the territory to promote the many archeological sites and Italian monuments. His major area of interest was in fact Etruscan art and its relationship with classical art, both Roman and Greek.

Between 1927 and 1928, he conducted an archaeological excavation in Sovana, Tuscany.

In 1935, together with Carlo Ludovico Ragghianti, he launched a magazine called *La Critica d'Arte* to host debates about the storical/artistic field. From a political point of view, the magazine was greatly influenced by the liberal ideas of the philosopher Benedetto Croce, and for this reason it was suppressed by the Fascist regime in 1943.

In 1940, he was invited by Gerhart Rodenwaldt to speak at a conference on classical art; the ideas of Bianchi Bandinelli deeply changed the understanding of classical art and influenced the work of scholars in the following years.

Several of his most relevant articles were collected by the magazine *Storicità dell'arte classica* in 1943 (See Bianchi Bandinelli 1943). Through those articles, we can summarize the intellectual work of Bianchi Bandinelli: the importance of the connection between artistic facts and historical substrate and the attention for the personality of the artists. Bianchi Bandinelli was also a follower of the teachings of Bernhardt Schweitzer, a German classical archaeologist and professor.

Between the years 1948 and 1959, he promoted several initiatives: he tried, with no results, to reform the *modus operandi* of the government department responsible for monuments and other treasures; he fought against the reconstructions promoted by the government that often, because of economic interests, ended up damaging the monumental and artistic heritage of the country. He was also very determined when expressing his ideas regarding classical art, determination that often led to debates with other scholars, such as Otto Brendel.

In the early 1960s, he started a magazine called *Studi Miscellanei*. He also founded *Dialoghi di archeologia* in 1967 in order to publish the contributions of younger students. In fact, despite

having left the university in 1964, he continued to mentor students. Andrea Carandini and Mario Torelli were among his followers, and their work is still a reference for university students.

He dedicated the last years of his life to the publication of some of his most important books (See Bianchi Bandinelli 1963, 1969, 1970, 1973 and 1976); this work summarizes his thoughts as an archaeologist and art historian. He highlighted how the historical and artistic heritage had to be interpreted taking into account its various levels, since each side of an artistic object would reveal a specific element: social, economic, and political.

Some of his ideas may be considered dated by looking at more recent studies, but the results of his dedication in the fields of archeology and history of art have surely provided his own students and future researchers with a solid base for their studies).

Banpocun, Archaeology of

Li Liu
Department of East Asian Languages and Cultures, Stanford University, Stanford, CA, USA

Introduction

Banpocun (Pan-p'o-ts'un) or Banpo is a site of the Neolithic Yangshao culture, located near Banpo village on the eastern bank of the Chan River, east of Xi'an, Shaanxi province, China. The entire site is estimated to be c. 5 ha in size, of which an area of 1 ha was uncovered during five seasons of excavation carried out from 1954 to 1957, led by Shi Xingbang of the Institute of Archaeology at the Chinese Academy of Sciences (Fig. 1). Archaeological deposits were divided into two phases. The early phase contained very rich material remains and was named the Banpo variant (*leixing*), dating to c. 4800–4300 BCE. Fewer ruminants were found from the late phase, named the Xiwangcun variant or Late Banpo variant, generally dating to c. 3500–3000 BCE (Institute of Archaeology, Chinese Academy of Sciences 1963). The entire excavated area of the Banpo site has been preserved as China's first on-site museum, the Xi'an Banpo Museum, which was first constructed in 1958 and rebuilt in 2006. Banpo has been further excavated in recent years, but a new excavation report has not yet been published.

Definition

Banpo is the first Yangshao culture site excavated on a large scale, providing rich data for understanding the economy, culture, and social organization of a Neolithic settlement. It is the type site

Banpocun, Archaeology of, Fig. 1 Excavation of the Banpo site

of the Banpo phase, and many contemporary sites sharing similar settlement layout and material assemblages later have been found over a large region in the middle Yellow River valley.

Key Issues/Current Debates/Future Directions/Examples

Settlement Layout

The residential area of the Banpo settlement is located in the center of the site, about 3 ha in area, including 46 buildings, more than 200 ash pits (mostly used as storage before abandonment), 2 livestock pens, and nearly 70 children's burial urns. Dwellings appear to have been divided into two clusters, separated by a shallow ditch, 1.5 m deep and 2 m wide. Each dwelling cluster consisted of one large building, up to 160 m^2 in size, surrounded by a number of medium and small structures, measuring 30–40 m^2 and 12–20 m^2 in size, respectively. The residential area was fortified by a moat, 5–6 m deep and 6–8 m wide. To the north of the ditch was a cemetery, and to the east were pottery kilns (Fig. 2).

The dwellings of the Banpo phase were either semisubterranean or at ground level. Each house had a hearth at the center and a doorway opening to outside. All the structures were built with wattle-and-daub walls and foundations, and the upper walls and roofs were supported by wooden posts. These houses were mostly circular structures, but a few were square or rectangular in shape (Fig. 3).

A population level of 5–600 for the entire village has been estimated by the excavator mainly on the basis of the extent of the settlement and the sizes and layout of the houses. The actual population size, however, is difficult to assess, because a large part of the settlement has not been excavated.

Material Remains

Ceramics (more than 500,000 potsherds) are the most numerous material remains excavated, accounting for 80% of the artifactual assemblage at Banpo. Pottery was probably made on site, suggested by the presence of six kilns. Nearly 1,000 vessels have been restored and are classified into four categories, including serving receptacles, water containers, cooking utensils, and storage vessels. Ceramics are mainly reddish or orange in color, some painted with human, animal, plant, or geometric designs (Fig. 4).

Twenty-two incised symbols have been found on the black band near the rim of pottery *bo* bowls (Fig. 5). They occurred singly, perhaps identifying

Banpocun, Archaeology of, Fig. 2 Model of the Banpo settlement

Banpocun, Archaeology of, Fig. 3 Reconstruction of a Banpo house

Banpocun, Archaeology of, Fig. 4 Painted pottery vessel from Banpo

the makers of the pottery or possibly the owners. Such pottery marks have been found at several Yangshao culture sites, and some of these forms appear to resemble certain numerals in the oracle-bone inscriptions of the Shang dynasty dating to the late second millennium BCE. It is possible that the Yangshao pottery signs were one of the sources of the Shang writing, but these pottery marks have not normally been regarded by archaeologists as indicating the contemporary existence of a writing system.

More than 5,000 tools were excavated from the site, variously made of stone, bone, deer antler, and pottery. The tool types include axe, adze, spade, knife, grinding stones (slab and hand stone), arrowhead, spearhead, harpoon, net-sinker, and fishhook. They have been classified into three categories, based on their presumed functions, as agricultural, hunting-fishing, and craft-manufacturing implements.

Agriculture appears to have played an important role in the subsistence economy. Carbonized remains of foxtail millet (*Setaria italic*) were found at the site in significant quantities; cabbage

Banpocun, Archaeology of, Fig. 5 Banpo pottery marks

seeds (*Brassica* sp.), hazel nuts, chestnuts, hackberry seeds, and pine nuts were also present. Other types of plants may also have been used by the Banpo people; but due to the absence of flotation method at the time of excavation, floral remains were not systematically uncovered.

Matting, basketry, and weaving were part of the craft production, evidenced by impressions of baskets, mats, and textiles on the bottoms of pottery vessels. A large number of spindle whorls, a type of weaving tool, have also been found at the site. It is unclear exactly what materials were used for making textiles at Banpo, but traditionally hemp and kudzu were among the indigenous plants used for weaving in China, as mentioned in ancient texts, such as *The Book of Odes*.

Many animal bones have been found at the site, identifiable as mammals, birds, and fish. Pig (*Sus domestica* L.) and dog (*Canis familiaris* L.) were clearly domesticated. Bones from many species of wild animals were present, including two types of deer (*Pseudaxis hortulorum* Sw. and *Hydropotes inermis* Sw.), sheep (*Ovis* sp.), bovine (Bovidae indet.), horse (*Equus* sp.), fox (*Vulpes* sp.), rabbit (*Lepus* sp.), gazella (*Gazella* sp.), chicken (*Gallus* sp.), and carp (Cyprinidae indet.). Pig bones were the most numerous in the faunal assemblage, followed by Chinese river deer (*Hydropotes inermis* Sw.). Hunting and fishing were important subsistence activities as evidenced by a great variety of wild animal remains and numerous arrowheads, harpoons, net-sinkers, and fishhooks.

Burials

A total of 174 adult burials and 73 children's urn burials have been excavated. Adult burials were found in pit graves, mostly located in the cemetery. Among 118 nondisturbed burials, 71 contained grave goods. Except for two cases in which two males and four females, respectively, were interred, each burial usually contained one skeleton in an extended position with the head pointing to the west or northwest. Grave goods consist mostly of pottery, ranging between one and 17 items, with an average of 5–6 pieces in each burial.

Children's urn burials have been found mainly near houses. They were associated with no funerary items, except one case which contained a small pot. It is noteworthy, however, that a burial belonging to a child of about 3–4 years old was furnished with an oblong wooden coffin and contained six ceramic vessels, three stone pellets, an earring, and a set of 76 bone beads girdled around the waist. This burial, dating to the late Banpo phase, was unique in terms of its rich furnishing, suggesting that social stratification may have emerged during the late phase of the settlement's occupation.

Social Organization

Banpo society was evidently egalitarian in nature during its early phase. There is no indication of social hierarchy present in the burial or residential remains. This site, however, has been routinely described by archaeologists in China as a typical Neolithic matriarchal or matrilineal settlement (see the Xi'an Banpo Museum website:

http://www.bpmuseum.com/en/), as opposed to the patriarchal or patrilineal society that presumably developed in the late Neolithic period. The concept of matriarchal society, primarily based on the nineteenth–century evolutionary theory proposed by Henry Lewis Morgan (1877, *Ancient Society*) and Friedrich Engels (1884, *The Origin of the Family, Private Property and the State*), was systematically introduced to China by Guo Moruo (1930) in the 1930s. Banpo was the first archaeological case in which Chinese scholars attempted to employ such a theoretical framework to interpret Neolithic social organization, in support of Marxist doctrine.

The Banpo excavator argued that matrilineal rules of descent are reflected in the two collective burials at the site, one each exclusively of females or males, and that this pattern contrasts with the single-male or single-female burial pattern characteristic of the monogamous family in patrilineal society. The rich child burial was interpreted as belonging to a girl, indicating that females enjoyed a high social status then. The settlement pattern was also described as arranged in a way suitable for the pairing marriage, believed to have been practiced in a matrilineal society (Institute of Archaeology, Chinese Academy of Sciences 1963: 226–33). The statement that the Yangshao culture was a matriarchal society soon became a standard phrase adopted in many archaeological publications, although evidentiary support is lacking in the archaeological record of some cases (Yan 1989). The reported evidence for matriarchal practice at Banpo is clearly less than convincing. For example, the rich child burial said to be of a girl is problematic, as the sex of a skeleton 3–4 years old cannot be determined. Although some criticisms were made, demonstrating faults in both theory (Pearson 1988; Tong 1998: 262–72) and applications (Wang 1983, 1987), the classical evolutionary model was commonly accepted among Chinese archaeologists then and has continued to be influential, but to a lesser extent, today (e.g., Institute of Archaeology, Chinese Academy of Social Sciences 2010: 204, 413, 652–3).

Barley: Origins and Development

Dorian Q. Fuller and Alison Weisskopf
Institute of Archaeology, University College London, London, UK

Basic Species Information

Barley (*Hordeum vulgare* L.) Poaceae derives from the Old English *baere* related in origin to the Latin *farina* or flour (Ayto 1990) and is known variously as *da mai* (China), *orge* (French), *gerste* (German), *orzo* (Italian), and *cebada* (Spanish) (van Wyk

2005). Barley is a major crop in global agriculture. Modern statistics (e.g., from faostat.fao.org) indicate that barley production globally follows only wheat, rice, and maize. Barley can be turned into breads and porridges, as well as beers and whiskies.

Barley was one of the founder crops of early agriculture in Southwest Asia and parts of the earliest farming systems that spread across Neolithic Europe, North Africa, and the Indus Valley. Its wild progenitor is *Hordeum spontaneum* K. Koch, which occurs widely in the eastern Mediterranean eastwards to Central Asia in the open woodland steppe through to the taller grass steppe zone (Hillman 2000; Harris 2010). Wild populations further west, such as in the Maghreb region of North Africa as well as some of those on its eastern margins, may or may not be aboriginally wild but could be feral populations. Barley is a generally more tolerant cereal than wheat, with which it is often found. Barley can be grown on more saline soils and with lower rainfall. It can also tolerate colder conditions than wheat. Thus, barley has reached to higher altitudes and higher latitudes than wheat (see Fig. 1).

Major Domestication Traits

Genetics and archaeology combine to imply that barley was domesticated more than once across the greater Near East, with three origins a likely minimum (Fuller et al. 2012). All are located across Southwestern to Central Asia (Fig. 1). Such evidence includes two genetic variants that make non-brittle domestic-type ears, and several other gene frequencies have geographic structure suggesting differences between east and west (Morrell and Clegg 2007). Genetic differentiation suggests a western Levantine domestication area and an eastern domestication, perhaps in the greater Iranian plateau region. While most wild and cultivated barleys are grown over the winter and flower in the spring, controlled by day length, other varieties have lost the linkage of day length to flowering and are well suited to spring/summer cultivation at higher latitudes or altitudes. These photoperiod-insensitive (summer) barleys derive from domestication of a separate wild population in the mountains of Iran (Jones et al. 2008).

Barley: Origins and Development, Fig. 1 Map showing the approximate maximum limits of traditional barley cultivation (*thick dashed line*) in relation to its wild range (*gray zone*). The map differentiates likely eastern and western subzones within the wild range that had separate domestications, as well as the locations for the development of original photoperiod-insensitive barley in Iran. The *symbols* show representative archaeobotanical finds that chart the earliest spread of barley

Timing and Tracking Domestication

Archaeobotanical evidence tracks both the evolution of domesticated barley, at least with regard to its western Levantine origin. Sites in several parts of the Levant have reported evidence for pre-domestication cultivation, most often involving apparent arable weed flora associated with morphologically wild barley remains (Fuller et al. 2012). Such evidence goes back to the PPNA period (9700–8800 BCE). Subsequently there is evidence for gradual morphological change including the steady increase in the percentage of non-shattering barley rachis remains and in average grain size (width and thickness) of grain samples over time. Both lines of evidence point towards change between the Late PPNA (c. 9000 BCE) and the Late PPNB 7000–6000 BCE and indicate gradual domestication over a ~3,000-year period.

Archaeobotanical evidence for barley is widespread, allowing the spread of this crop to be tracked (Fig. 1). It was an essential part of the founder crop package that dispersed from the "Fertile Crescent" westwards to Neolithic Europe, starting about 7000 BCE and reaching the British Isles just after 4000 BCE. Similarly, it spread rapidly eastwards to the Indus Valley and Turkmenistan, where it is present by 6000 BCE. The dispersal into Egypt and up the Nile is later (c. 4000 BCE), while the spread of barley in monsoonal India or to southern Arabia took place after 3000 BCE. The first barley in southern India or China appears to date more recently than 2000 BCE.

Barley has evolved into a number of distinct varieties, illustrated diagrammatically in Fig. 2. Whether barley has 2 or 6 rows of grains on the ear and has free-threshing (naked) grains or hulled ones should be separable in archaeobotanical

Barley: Origins and Development, Fig. 2 Diagram of the main types of barley and evolutionary pathways between them. These are illustrated by potential archaeobotanical differences in grain and rachis morphology

remains (see Fig. 2). Wild barley normally has two rows of grains, and grains have tightly fitting hulls; this is a two-row, hulled, and shattering wild type. The first change with domestication is the loss of spike shattering, which can be tracked archaeologically with the recovery of tough rachis remains. Two changes that occurred after were the increase to six-row and the development of free-threshing (or naked) barley. While naked barley appears to have evolved once, originally in early two-rowed forms, 6-row barley has evolved 3 times, including local independent parallel mutations in eastern Asia and the western Mediterranean (Komatsuda et al. 2007).

Thus there are three main variant genes that create six-row barley (*Hordeum vulgare* var. *hexastichium*), a condition that only exists among domesticated races, and these also show east/west patterning (Tanno and Takeda 2004). In ancient Nubia there was a unique, now lost, barley that has six-row architecture and chaff and only produces two grains. Palmer et al. (2009) demonstrate that this has 6-row genetics and may represent a local reversion as adaptation to the extreme aridity in Nubia. Recent work on genetic variation in wild barley (*Hordeum spontaneum*), which unlike wheat has a large eastern range extension into Pakistan, Afghanistan, and Central Asia, shows systematic variation in allele frequency. Morrell and Clegg (2007) have demonstrated that allele frequencies in cultivated landraces are best explained by two origins from differentiated wild barley populations, one of which was in the Levant, while the other is suggested to lie somewhere from Zagros mountains eastwards towards Central Asia.

Hordeum agriocrithon, a wild six-row barley of the Tibetan Plateau, is likely to be a feral derivative of domesticated 6-row barley or a hybridization from a 6-row crop into two-rowed *H. spontaneum*, rather than truly wild (Tanno and Takeda 2004). All naked barleys, including the naked 6-row commonly grown in the Tibetan Plateau, share the same nude genetic mutation (Pourkheirandish and Komatsuda 2007). This suggests that they derive this trait from the early naked barleys that had appeared by the Late Pre-Pottery Neolithic of Southwest Asia.

Barrow Area Sites: Nuvuk, Utqiaġvik, and Birnirk

Anne M. Jensen
UIC Science LLC, Barrow, AK, USA
Department of Anthropology, University of Alaska Fairbanks, Fairbanks, AK, USA

Introduction

The Utqiaġvik (formerly Barrow) area is home to several important archaeological sites. Among these are the sites that fall under the general heading of Utqiaġvik, including Utqiaġvik proper, Ukkuqsi, and Kugok; Nuvuk; and Birnirk (type site of the Birnirk culture) (Fig. 1).

The earliest "archaeology" in the Utqiaġvik area was done by nonprofessionals, often by purchasing artifacts from residents who excavated for pay. Notable among them were Murdoch (1892), Stefansson (1914), Wissler (1916), Ford (1959), and Van Valin (1941), a Barrow schoolteacher.

James A. Ford excavated at Nuvuk in 1932, Utqiaġvik in 1932, and Birnirk in 1936. Ford's report (1959) on his excavations on the Chukchi coast defined harpoon head typology for this region and provided extensive and well-illustrated descriptions of artifacts from Birnirk through contact period sites.

Definitions

Utqiaġvik

Utqiaġvik is the traditional Inupiaq name for the community formerly known as Barrow. The name Utqiaġvik (or Utkiavik) also refers to the archaeological component of the community as a whole, which also includes two areas that are sometimes referred to separately, Ukkuqsi and Kugok. The precontact settlement was on the Chukchi Sea coast, concentrated on high ground on either side of Kugok Ravine. It consisted of at least 60 mounds, which had been built up in part by superposition of sod-covered semi-subterranean houses.

Utqiaġvik has a very limited number of radiocarbon dates, given the amount of excavation that has taken place at the site. However, it has long been recognized as having been occupied from Late Western Thule times until the present day, and the majority of the material excavated from the site corresponds to this understanding. However, Birnirk burials were recovered from the Kugok area of the site as early as 1932 (Ford 1959), and more recently a Western Thule burial was recovered from a pit dug through the floor of a Birnirk house at Ukkuqsi (Zimmerman et al. 2000). Lithics that have been identified as Arctic Small Tool Tradition (ASTt) have also been recovered from Utqiaġvik, indicating that the area was being used at least as early as 4000–5000 BP.

Utqiaġvik was originally mapped by Ford in 1932, with more extensive mapping by Stanford in 1968 (who began the mound numbering system) and the Utkiavik Archaeological Project (UAP). A number of the mounds have been hidden or destroyed by modern construction of roads. All portions of the site except Kugok are threatened by coastal erosion and sea level rise.

Utqiaġvik

In 1981 through 1983, major excavations were carried out at the Utqiaġvik site (Hall and Fullerton 1990). These excavations concentrated primarily on houses, although some work was done on activity areas outside the structures. The vast majority of the material excavated was late precontact and postcontact. The excavations of Mound 34, which included a prehistoric *qargi* (ceremonial center), were published in a monograph (Sheehan 1997).

Barrow Area Sites: Nuvuk, Utqiaġvik, and Birnirk, Fig. 1 Map of Utqiaġvik-area sites

In 1986, a number of blocks of tundra from the Utqiaġvik site slumped onto the beach. In 1990, a salvage excavation of the single remaining slump block was carried out. Radiocarbon dates averaged 1281–1395 calAD (Mason 1991).

A number of human remains have been recovered from Utqiaġvik. Ford recovered the frozen and partly desiccated bodies of two women from the floor of a house that some Utqiaġvik residents had begun excavating in imitation of Ford's work (Ford 1959). The Utqiaġvik Archaeology Project recovered a number of individuals in a similar state of preservation from a collapsed house in Mound 44 at Utqiaġvik (Newell 1984). These were catastrophic, not deliberate, burials.

Kugok

Kugok is the name of the ravine that bisects the settlement of Utqiaġvik. It contains a stream that was a summertime freshwater source for the residents. The name is generally applied to a group of mounds at the head of the ravine, which contained Birnirk burials. Van Valin may have recovered some Birnirk burials in this area. Ford reported the recovery of 15 individuals (Ford 1959:25–30). Four additional individuals were recovered by the Utqiaġvik Archaeological Project (UAP) in 1981.

Ukkuqsi

Ukkuqsi is the name given to the subarea of Utqiaġvik located around the mouth of Kugok ravine, particularly a large mound on the south side of the ravine. In 1994, the frozen body of a young girl was exposed by erosion (Zimmerman et al. 2000). The autopsy indicated that she most likely died of starvation and had experienced disabling health issues in life. Artifacts recovered during excavation ranged in age from postcontact glass beads found at and near the surface to two harpoon heads and a Birnirk throwing board from the floor of a house through which the meat pit in which the little girl had been buried had been cut.

Nuvuk

Nuvuk is located at the tip of the Point Barrow spit. At contact, the settlement was larger than Utqiaġvik; the last residents moved away in the late 1940s. Until recently, Nuvuk had been considered a late

Barrow Area Sites: Nuvuk, Utqiaġvik, and Birnirk, Fig. 2 Excavating at Nuvuk. Burial excavations foreground and test pit excavation in rear. Beaufort Sea in background. View northeast

precontact through postcontact site and therefore of little archaeological interest. Recent work by a large community archaeology project (Jensen 2009a, b, 2012) has revealed the largest known cemetery in North Alaska, with graves dating from Early Thule (possibly late Birnirk) through late Western Thule. Radiocarbon dates on the graves range from 720–980 calAD up to 1640-present calAD, which accord fairly well with the direct dating of the individuals (Coltrain et al. 2016). That work also revealed a precontact/contact period work area located on lower ground at a distance from the graveyard and the winter village, with radiocarbon dates ranging from 1480–1670 calAD up to 1680–1930 calAD, and an artifact inventory including metal tools and imported wood, indicating some use after time of contact. There was also an earlier occupation at Nuvuk that contained the first evidence for Ipiutak north of Point Hope, including portions of two structures and faunal remains. Radiocarbon dates place it between 330 and 390 calAD. Nuvuk is currently the best dated of the Utqiaġvik-area sites (Fig. 2).

Wilbert Carter (1966) described Nuvuk in 1953 made up of 19 "locations" with indications of houses. Some had multiple houses or rooms, giving a total of 46 houses or meat caches. His work resulted in the recovery of a number of artifacts, which he interpreted as recent (i.e. pre- and postcontact Inupiat), although illustrations in some of his reports suggest that early material was present.

When the Nuvuk Archaeological Project (NAP) began excavation (Jensen 2012), the village had eroded, but graves were noted in the erosion face. Initial salvage excavations of these graves revealed what proved to be the precontact cemetery. An adjacent Christian graveyard has markers dating from the early 1900s. During the period immediately preceding contact Utqiaġvik-area residents had shifted to surface "burials." There is an extensive modern history of collection of human remains from the surface in the Nuvuk vicinity, which presumably removed many of these individuals from the Nuvuk mortuary precinct.

Barrow Area Sites: Nuvuk, Utqiaġvik, and Birnirk, Fig. 3 Some of Birnirk mounds from the air. Note Elson Lagoon waters encroaching. View NNW

The human remains excavated from Nuvuk by the NAP were carefully documented by physical anthropologists prior to their reburial. Samples were retained for ancient DNA (aDNA) extraction, stable isotope analysis, and radiocarbon dating (Coltrain et al. 2016, Raff et al. 2015, Tackney 2016).

Birnirk

Birnirk (Piġniq in Inupiaq) is located at the base of the Point Barrow spit, between Elson Lagoon and the Chukchi Sea. It is made up of a group of 16 mounds near the shore of the lagoon, separated from the Chukchi Sea by a series of gravel beach ridges. Birnirk is the type site of the Birnirk culture and is currently designated a US National Historic Landmark. Some parts of the site are threatened by sea level rise (Fig. 3).

James Ford's work indicated that the major occupation at Birnirk was relatively early, predating what was then known of occupation at Utqiaġvik. However, some of Carter's later work, as well as explorers' accounts, suggest that the site was occupied to some extent past the time of contact. Radiocarbon dates from the site are range from 680–890 calAD to 1460–1650 calAD. However, most dates, including those on harpoon heads chosen to date the transition between Birnirk and Thule (Morrison 2001), cluster between 900 and 1200 cal AD. Ford produced very detailed (1′ contour) maps of Birnirk. These maps were published together with his description of his 1930s work (Ford 1959). This remains the best published information on the site.

Stefánsson reportedly recovered one individual from Birnirk, but no further documentation is available. Ford (1959) recovered a number of individuals here, as did Carter, although it is not clear if they were the result of deliberate burials. The stratigraphy of the mounds at Birnirk is extremely complicated. It is unclear if the human remains were recovered from within houses, as in the cases at Utqiaġvik, or were deliberately buried in grave structures, as seems to have been the case at Nuvuk and Kugok.

Key Issues/Current Debates/Future Directions/Examples

A key research issue is clarifying the occupational history of these sites. Only Nuvuk has a reasonable suite of radiocarbon dates (Jensen 2009a, 2009b). Both Birnirk and Utqiaġvik could benefit from a program of systematic dating of well-chosen existing specimens. However, modern

excavation standards are quite different than when Birnirk was last excavated, so some controlled excavation would help. There is a large well-excavated collection from Utqiaġvik. However, the existence of multiple Birnirk burials at Kugok, coupled with the Birnirk finds from the house floor at Ukkuqsi, suggests that there was at least a small Birnirk occupation at Utqiaġvik, which apparently was not encountered by earlier excavators. Resolving this issue will make it feasible to address other questions.

One question of interest concerns changes in the material culture found at the sites, and whether they relate solely to in situ cultural development or whether a population replacement from elsewhere was involved. The aDNA studies from Nuvuk (Tackney 2016), coupled with modern DNA studies of the North Slope (Raff et al. 2015), suggest that population replacement was not a major factor. Improved chronological control should better identify the timing of changes in material culture, as well as apparent changes in social and cultural organization. This will permit these changes to be situated in an environmental context, in order to investigate the human ecodynamics.

A related question is what role the Utqiaġvik area played in the development of the Thule culture and whether it was the source for the Thule migration. Various conflicting theories exist, an extreme one of which includes a multicentury abandonment of the Utqiaġvik area. Although the stratigraphy at the sites, the known radiocarbon chronology, and the aDNA evidence appear inconsistent with this scenario, better understanding of individual site chronologies will clarify the situation.

The broad outlines of paleoeconomy in the Utqiaġvik area are understood from prior excavations. However, none of the sites has had a rigorous zooarchaeological study carried out. Midden deposits still exist at Birnirk and Utqiaġvik where productive studies could be carried out.

All of these sites are severely threatened by coastal erosion and sea level rise. The warming of permafrost and concurrent deepening of the active layer is also a major threat to the generally excellent preservation that currently exists at these sites.

Basilica in Classical Archaeology

Francesco Marcattili
Dipartimento Uomo e Territorio Sezione di Studi Comparati sulle Società Antiche, Università degli Studi di Perugia, Perugia, Italy

Introduction and Definition

The Latin term basilica is a transliteration of the Greek Βασιλική ("belonging to the king", "royal") and generally refers to a wide and sumptuous covered hypostyle hall, mainly associated with a forum square (Gros 2001: 260–89, with bibliography). This definition is ably demonstrated by an important inscription from the Roman theater of Iguvium (modern Gubbio) (*CIL* XI.5920a-b = *ILS* 5531: "Cnaeus Satrius, son of Cnaeus, a colonial commissioner, provided the *basilicae* with paneled ceilings") ("*C*]*n*(*aeus*) *Satrius Cn*(*aei*) *f*(*ilius*) *Rufus*, *IIIIvir iur*(*e*) *dic*(*undo*)/*basilicas sublaqueavit*. . ."). The term can also be employed to designate rooms with the same spatial and architectonic characteristics belonging to other public, and even private, complexes (Gros 2003, 2004). As a matter of fact, as the *basilicae forenses*, the two *basilicae* of Gubbio's theater, built flanking the scenic sector during the early Augustan period, constituted large and luxurious halls provided with columns, roofing, and pavement, designed for the reception, passage, and shelter of citizens in a manner similar to the more common *basilicae* of forum spaces. The basilica, therefore, was a monumental, multivalent space that, in the case of a *basilica forensis*,

added the basic functions of hospitality and accommodation to the judicial, administrative, and commercial activities specifically linked to the forum and which originally had been conducted outdoors.

Key Issues/Current Debates/Future Directions/Examples

The typology, elaborated in Rome from the end of the third century BCE onward, was most likely inspired by similar structures of the Hellenistic eastern Mediterranean (e.g., Wilson 2005). The basilica gradually replaces *atria* with *tabernae* that would normally border forum squares of the middle Republican period. These buildings were modeled along the lines of the traditional Italo-Roman atrium house and were mostly private property that could be rented for public activities, such as auctions, or religious activities, such as the *Tubilustrium* (Varro *LL* 6.14). The *atrium Regium* of the Forum Romanum, located between the *forum Piscarium* and the *Comitium* in the area of the Basilica Aemilia, is considered, also thanks to the onomastic correspondence (*aule basilike* = *atrium Regium*), the "ancestor of the Roman basilicas" (Gros 2001: 260–4). The construction of Basilica Porcia in 184 BCE, the first to be designated, as many *atria* previously, with the gentilician name (*nomen gentilicium*) of the founder (*De viris illustribus*, 47), has been realized at the site of "*atria duo* [. . .] *et quattuortabernas*"; and to be more precise at the site of *atrium Maenium* and *atrium Titium*, purchased by Cato the Elder with public funds in the area of the *Lautumiae* (Liv. 39.44.7). An analogous development takes place in Republican colonies as demonstrated by the forum of Cosa, which is bordered on three sides by *atria publica* that anticipate the construction of the basilica (c. 120 BCE) (Brown et al. 1993: 207–45).

The influx of Hellenistic traditions soon rendered the buildings of the republican tradition both inadequate and outdated, an inadequacy that led to the genesis and elaboration of the prototypical basilica. This transformation is evident in the monumental center of Rome in the space of only a few decades, with the identification, attested in Plautus (*Curculio* 1–472; *Captivi* 813–815), of the *atrium Regium* as a basilica. The construction of the Basilica Porcia (184 BCE) and the Basilica Aemilia (179 BCE during the censorship of M. Fulvius Nobilior) soon followed, as did the Basilica Sempronia (169 BCE). All of these building projects conferred both effectiveness and regularity to the Forum Romanum. The complex archaeological research into the first urban *basilicae* seems to demonstrate the gradual architectural development of this typology, which quickly acquires monumentality thanks to the installation of internal arcades erected to delimit wider naves and through the longitudinal axis of the building with respect to the square (Coarelli 1985: 135–66). This collocation may be noted in the several cities of Republican Italy, including Cosa, Alba Fucens, Ardea, and Aquileia, although it must be noted that one of the best known *basilicae* of the late second century BCE, that of Pompeii, opens up on to the city's forum along one of its short sides (Ohr 1991).

The basilica of Pompeii is of great interest for many reasons: it preserves in the substantially intact interior one of the recurrent elements of forum *basilicae*, namely, the *tribunal* (David 1983), which was a high podium (sometimes with columns) where magistrates used to sit during judicial proceedings. The example at Pompeii, furthermore, anticipates with some of its architectonic and planning details the model of basilica that Vitruvius would postulate in the late first century BCE (Gros 1984) when he planned the colony of Fanum Fortunae, an example that remains unknown to archaeology (*Arch*. 5.1.6–10). The isolation of the internal space by means of continuous walls at the expense of the more common arcades and the use of a so-called "colossal" order for the internal colonnade are principal factors of the analogy drawn between Fanum Fortunae and Pompeii. The basilica of Pompeii, however, respects the Vitruvian prescriptions in the organization of the central space and for the presence of the *tribunal* as well. The position of the building is different compared to the forum square and, accordingly, the *tribunal* inside the basilica that in the Vitruvian model is

located in relation with an *aedes Augusti* in a quadrangular exedra that opens at the end of the minor, central axis. The pattern of the exedra with judicial, administrative, and/or religious functions will be replicated with success in many *basilicae* starting in the early Imperial period, as demonstrated by the cases of Rusellae, Lucus Feroniae, Iuvanum, Saepinum, Herdonia, and Gnathia as discussed by Gros (2001: 270).

Rooms with apsidal or even more simple quadrangular *exedrae*, very common annexes inside the basilica starting from the early Imperial period, were used as *tribunalia* or as traditional curia (Balty 1991), but, as shown by the Vitruvian basilica with its *aedes Augusti*, they could include inside statues of dynasts ideally destined to protect and guarantee the correct execution of administrative and judiciary activities (cf. also the statuary groups of the *basilicae* of Velleia, Otricoli, and Bologna).

"The basilica is provided with an apse defined as a *tribunal*, a curia, and a sanctuary of Augustus at the same time, it is probably the monument which architecture expresses more effectively compared to others the new hierarchy of functions imposed by the political structure at the beginning of the Imperial period. No other composition allows us to appreciate better the sense of the evolution of power that took place between the end of the Republic and the beginning of the Empire; the consensus organization that implied an institutional and urban relationship between the sacred and the political at the beginning is now overcome by a subordination of the judiciary to the sacred, where the sacred assumes the forms of the Imperial cult [. . .] This takeover of judiciary (*tribunal*) and administrative (curia) functions under the aegis of power is typical of the monarchical drift of a system in which the local autonomies traditionally recognized by the citizen status have the right to exist only in a restricted and symbolically controlled framework . . . ." (Gros 2001: 296–7).

In the meantime, from the final decades of the first century BCE, the *basilicae* that bordered the Forum Romanum were also linked with more or less radical projects dedicated to the Imperial family and their glorification. The Basilica Aemilia, the only one among the more ancient Roman *basilicae* to survive in any measure, which for centuries had celebrated the name of the famous Republican *gens*, had a two level arcade dedicated to Caius and Lucius Caesar added on its facade facing the square in front of the *tabernae novae* (14–2 BCE) (Coarelli 1985: 173–89). This construction replaced arcades that were already present from the previous chronological phases (Coarelli 1985: 201–9). An even more decisive action took place on the southern side of the Forum Romanum that had been partially occupied by the Basilica Sempronia since 169 BCE. It was now removed and replaced by Basilica Iulia, started by Julius Caesar and completed by Augustus; it was thereupon destroyed by fire almost immediately and was therefore rebuilt and rededicated to the emperor's adopted children (12 CE).

The planimetric organization of these two, exceptional urban *basilicae*, numbered among the most beautiful buildings ever built in Rome, was similar and, in clearly emphatic forms, also repeated the common pattern of the basilica type: a wide central room with a major height (*spatium medium*), surrounded by one or more aisles on which could stand galleries or an ambulatory and anticipated by a facade or *porticus* opening toward the forum's square. As building types became progressively more monumental during the Imperial period, an even more radical application of this tendency may be observed in the Basilica Ulpia of the Forum of Trajan (106–113 CE), which was, at the time, the largest basilica ever built with 8500 m^2 of covered space and five naves (Fig. 1). The main novelty of the Basilica Ulpia is represented by the presence of two apses at the nave's sides, and this pattern will have great fortune into the realization or renovation of some important peripheral *basilicae*, mostly in Africa (e.g., Aquileia, Augusta Raurica, Leptis Magna, Bulla Regia, Sabratha, Volubilis) (Gros 2001: 282–7).

If, as observed, in Rome and in the urban centers of the western Mediterranean, a strict relationship existed between the basilica and the *porticus* (Nünnerich-Asmus 1994), this relationship is not well attested in the eastern provinces of

Basilica in Classical Archaeology, Fig. 1 The Basilica Ulpia in the Forum of Trajan. (From Gros and Torelli 2007: 227, Fig. 121, with kind permission)

the Roman empire. As a matter of fact, considering, for example, the plans of the *basilicae* of Ephesus and Smyrna, it is difficult to formally distinguish them from the numerous, long *stoai* that usually bordered the civic *agorai*. On the other hand, the three *basilicae* of the *agora* of Corinth, a *colonia libertinorum* that became capital of the Roman province of Achaea under Augustus, are linked to the Western rules.

A "normal" pattern that, applied also to the *basilicae* of other provincial capitals such as Tarragona and Carthage, will have a long life in the West, partially transformed under the influence of the architecture of public baths – *basilicae thermarum* are also well known – and by the need for dynastic propaganda implemented with more and more daring and emphatic forms. In Rome the Basilica of Maxentius (or Basilica Nova) was completed by Constantine I. The great nave, covered by three cross vaults, does not adopt the usual side aisles with columns, but rather employs a system of three large rooms per side interconnected and covered by mighty barrel vaults, according to construction indications that

resemble closely the colossal rooms of the Imperial baths. The long central room, whose rhythm was quite different from the side rooms, was focused at its western side on an apse that hosted a colossal acrolithic statue of the emperor as Zeus enthroned (the fragments of which are now housed in the Palazzo dei Conservatori of the Capitoline Museums in Rome). This statue, god on earth with his gaze cast *instinctu divinitatis* toward the sky, together with analogous *simulacra* and apses, must have contributed to select the basilica as the ideal building type to celebrate the Christian god as well.

Bass III, William M.

Murray K. Marks
Department of Pathology, Graduate School of Medicine, University of Tennessee Health Science Center, Knoxville, TN, USA

Basic Biographical Information

Education and Professorships

Dr. William "Bill" Bass (Fig. 1) was born in 1928 and raised in Virginia, receiving a B.A. in Psychology from the University of Virginia and his MS in Anthropology from the University of Kentucky. He had already earned two university teaching positions in departments of anthropology a year and a half prior to completion of his doctorate from the University of Pennsylvania in 1961. These appointments were Instructorships at the Universities of Nebraska and Kansas. Bass's graduate mentors, Drs. Charles Snow and Wilton Krogman, heavily influenced him throughout his career. With the Ph.D., he earned Assistant, Associate, and full Professorships

Bass III, William M., Fig. 1 Dr. William M. Bass, III, in the Human Osteology Laboratory at the University of Tennessee, Knoxville, c. 1978

during his tenure at Kansas from 1961 to 1971. He came to the University of Tennessee in 1971 to head the Department of Anthropology and develop a graduate program, remaining chairperson until 1992. Bass became Professor Emeritus in 1998, after 6 years as Professor and Director of the Forensic Anthropology Center.

Major Accomplishments

Bioarchaeology

Dr. Bass guided his student excavation crews during the summers of 1956 through 1959 pioneering the formulation of prehistoric Plains mortuary site archaeology. As the physical anthropologist for the Smithsonian Institution's River Basin Survey, Bass and his students excavated numerous cemetery sites, chiefly in South Dakota at Sully, a protohistoric Extended Coalescent site, Mobridge; a protohistoric Postcontact Coalescent, Le Beau phase site; and Leavenworth, a historic Arikara site, uncovering hundreds of burials that produced thousands of human skeletons in exquisite states of bone and dental preservation. From 1961 until 1970, Bass was field director for the National Science Foundation and National Geographic Society that serially funded field excavations of prehistoric skeletal remains from the Northern and Central Plains region, particularly, South Dakota.

Half a century of graduate students from Kansas and Tennessee and numerous researchers studied these pristine skeletal collections creating data sets and quantitative and qualitative methods and techniques to answer questions about the Plains people's prehistoric lifeways, from demography to pathology and warfare. Those students, Douglas Ubelaker, Walter Birkby, Richard Jantz, Pat Willey, and Ted Rathbun, to name a few, all continued studying becoming professors of human skeletal biology in both bioarchaeological and forensic contexts. In 1994, Douglas Owsley and Richard Jantz dedicated to Bass an exciting volume, *Skeletal Biology in the Great Plains*, culminating much of these results.

Dr. Bass's interest in bioarchaeology continued at the University of Tennessee where in the late 1970s he and Professor Walter Klippel directed, with US National Park Service funding, the excavation of a large Mississippian cemetery at the Averbuch site in central Tennessee. Similar to the Plains skeletal series, the Averbuch remains of nearly 1000 skeletons have provided a research base for numerous theses, dissertations, and research articles. A book that Bass initiated during

his tenure at Kansas, *Human Osteology, A Laboratory and Field Manual*, now in its 5th edition (Bass 2005), has served as a cornerstone text in the teaching of human osteology at both undergraduate and graduate levels.

Forensic Anthropology

Dr. Bass's initial exposure to forensic anthropology was with Dr. Charles Snow making a positive identification from a burned body, and Drs. Bass and Krogman are the only anthropologists who have examined the remains of the Lindbergh baby. The victim was the 20-month-old son of famed trans-Atlantic aviator Charles A. Lindbergh and his author wife, Anne Morrow Lindbergh. The child was kidnapped from the family home in 1932, and skeletal remains were discovered several months later.

These mentors sparked an interest that Bass formally developed into a graduate curriculum at the Universities of Kansas and Tennessee. While he performed human identification services in Kansas, a near, full-time shift of interest to forensic anthropology occurred when he became Head of Anthropology at the University of Tennessee. During this transition, Bass realized that academic departments of physical anthropology were producing new professors more rapidly than university positions could support. He also noticed an ever-increasing reliance among the pathologists, medical examiners, and coroners he was consulting with, for a resource with expertise in forensic osteology.

During his first year in Tennessee, Dr. Bass was exposed to several cases where the remains were neither skeletal nor fresh. This contrasted to his work in Kansas where most remains were skeletal. In 1977, the examination of Confederate Civil War Colonel William Shy, a casualty from the 1864 Battle of Nashville (Bass 1997), made a profound impression on Bass; science had no idea how long it took for soft tissues to decompose. Bass turned his research energy to studying soft tissue decomposition, the process of skeletonization, and requested an outdoor laboratory to document the process. By 1980, he began in earnest witnessing decomposition events firsthand with bodies donated from medical examiners. Time since death estimation became a steadfast research focus of a fledgling crop of Bass's graduate students dedicated to understanding this process.

The dual reputation of an engaging and theatrical teaching presence and a burgeoning avant-garde research program deciphering the stages in human decomposition combined to the granting of the prestigious award of National Professor of the Year in 1985 by The Council for Advancement and Support of Education. Subsequent to that recognition, Bass created the Forensic Anthropology Center, an endowed research program in the Department of Anthropology focusing on research in all realms of forensic anthropology, including archaeology and other diverse components of victim decomposition and scene dynamics.

As Dr. Bass's expertise and reputation in understanding decomposition strengthened because of his outdoor laboratory observations at the research "facility," he was summoned to examine more cases and venture estimations of time since death for medicolegal testimony. This prompted more cases, more research, and more students. Virtually everything we now understand about the entomological foundations of decomposition originated from studies initiated at Bass's facility by him and his students. Besides a comprehensive understanding of how temperature guides gross decomposition events, soft tissue histology from organ biopsy has been examined during the decomposition process along with soil and odor biochemistry and situational scenarios with burial, body position, clothing, coverings, fabric variety, trace evidence, cadaver dog exposure, and water submersion. In 1994, a symposium in honor of Dr. Bass was presented by his students at the American Academy of Forensic Sciences meeting, and the following year those papers were published in a special volume (see "References").

Bass, George Fletcher

Cemal Pulak
Institute of Nautical Archaeology (INA) at Texas A&M University, College Station, TX, USA

Basic Biographical Information

George F. Bass was born in Columbia, South Carolina, on 9 December 1932. He graduated from The Johns Hopkins University in 1955 with an M.A. in Near Eastern archaeology and attended the American School of Classical Studies at Athens, Greece, between 1955 and 1957. During that time he participated in preclassical excavations at Lerna in Greece and Gordion in Turkey. After serving in the US Army as a lieutenant in South Korea (1957–1959), he began doctoral studies in classical archaeology at the University of Pennsylvania.

In 1960, at the request of his department chairman, Rodney Young, Bass learned to dive prior to excavating a Bronze Age shipwreck of around 1200 BCE reported by journalist Peter Throckmorton off Cape Gelidonya, Turkey. That summer, with Throckmorton, Bass directed the excavation of the wreck, the first ancient wreck excavated in its entirety on the seabed and the first excavated and published by a diving archaeologist. With this excavation, Bass set the example for future underwater archaeological research by demonstrating that shipwrecks could be recorded and excavated to the same rigorous archaeological standards applied to terrestrial sites. Based on the ship's cargo of scrap bronze, and copper and tin ingots, Bass concluded that the ship was Canaanite in origin and that the role of Bronze Age Near Eastern seafarers had gone mostly unnoticed because their trade goods consisted primarily of raw materials, which left no trace in the archaeological record, because on arrival they were soon manufactured into artifacts characteristic of the importing cultures – a view now widely accepted, but radical for its time.

While excavating a seventh-century CE Byzantine wreck (1961–1964) and a fourth-century CE Late Roman wreck (1967–1969) at Yassıada, Turkey, Bass implemented new techniques and tools, including an underwater telephone booth, a submersible decompression chamber without surface support, and a method of mapping shipwrecks by stereophotogrammetry. In 1964, he launched the two-person *Asherah*, the first commercially built research submersible in the United States.

In 1964, Bass received his doctorate from the University of Pennsylvania and joined its faculty. In 1967, Bass's team was the first to locate an ancient shipwreck, with side-scan sonar, a second or first century BCE Hellenistic wreck near Yalıkavak, Turkey. He assisted the excavations of a Bronze Age city on Santorini, Greece, in 1968; spent a sabbatical year at the University of Cambridge (1969–1970); and in 1971 excavated a preclassical site in southern Italy, his last terrestrial excavation.

In 1973, Bass resigned from the University of Pennsylvania to form an institution devoted to the exploration and study of underwater cultural heritage, the American Institute of Nautical Archaeology (AINA). AINA's first field project was a Turkish-coastal survey that located a dozen ancient shipwrecks. In 1976, Bass affiliated AINA with Texas A&M University, which started a graduate program in nautical archaeology, a new branch of archaeology that has achieved academic recognition largely through his and his colleagues' work. A Distinguished Professor Emeritus at Texas A&M since 2000, Bass directed the Nautical Archaeology Program (NAP) until 1993. AINA – renamed the Institute of Nautical Archaeology (INA) in 1979 – became world-renowned by conducting underwater research on four continents. In 2000, INA added a research and conservation center in Bodrum, Turkey.

In the 1970s, Bass initiated the excavations of two shipwrecks of the American War of Independence: the American privateer *Defence* in Penobscot Bay, Maine, and the British "Cornwallis Cave Wreck" in the York River, Virginia, before turning the excavations over to other scholars. He was no less active in the Caribbean, initiating surveys and excavations in Jamaica and the Turks and the Caicos Islands, all of which he turned over to colleagues and students.

Between 1977 and 1979, Bass excavated an eleventh-century CE shipwreck at Serçe Limanı, Turkey, which was then the earliest known wooden hull built according to modern construction methods. In 1979, INA purchased the 65-ft, steel-hulled *Virazon*, which Bass had taken to Turkey on loan from the US Navy in 1964, and outfitted it with a recompression chamber and equipment for underwater surveys and excavations.

In 1984, Bass began the deepest large-scale excavation ever conducted under water, of a Bronze Age ship lost around 1300 BCE at Uluburun, Turkey. Its cargo of raw materials and personal possessions provided further evidence for Bass' theory of Bronze Age Near Eastern traders that he had proposed in his book on the Cape Gelidonya wreck. In 1985, Bass turned over the Uluburun excavation to another of his students.

Bass codirected with former students the excavations of the fifth-century BCE Tektaş Burnu wreck (1999–2001) and the sixth-century BCE Pabuç Burnu wreck (2002–2003) in Turkey. During that time, INA acquired a two-person submersible of revolutionary design, *Carolyn*, and built a 45-ft catamaran to support it in its successful surveys.

Major Accomplishments

Bass has been widely recognized for his significant achievements and contributions to the field of nautical archaeology. He has been awarded the Archaeological Institute of America's Gold Medal for Distinguished Archaeological Achievement (1986), the Explorers Club's Lowell Thomas Award (1986), the National Geographic Society's La Gorce Gold Medal (1979) and its Centennial Award (1988), the J.C. Harrington Medal from The Society for Historical Archaeology (1999), and the Historical Diving Society's Pioneer Award (2006). In 2002, President George W. Bush presented Bass with the National Medal of Science. The Archaeological Institute of America established a lecture series in his honor and presented him with the Bandelier Award for Service to Archaeology (2011); he was elected a fellow of the American Academy of Arts and Sciences in 2012. Bass received honorary doctorates from Boğaziçi University in Istanbul (1987) and the University of Liverpool (1998).

Bass has written, coauthored, and edited eleven books; published more than 200 scholarly and popular articles; and lectured around the world. His books include *Archaeology Under Water* (1966), *A History of Seafaring Based on Underwater Archaeology* (1973), *Archaeology Beneath the Sea* (1975), *Yassı Ada I: A Seventh-Century Byzantine Shipwreck* (1982), *Ships and Shipwrecks of the Americas* (1988), *Beneath the Seven Seas: Adventures with the Institute of Nautical Archaeology* (2005), *Serçe Limanı* I: *An Eleventh-Century Shipwreck* (2004), *Serçe Limanı* II: *The Glass of an Eleventh-Century Shipwreck* (2009), and *Archaeologist Beneath the Sea* (2012).

Bates, William Brian (Badger)

Christopher Wilson
College of Humanities Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

William Brian (aka "Badger") Bates was born in 1947 at Wilcannia, New South Wales (NSW). His mother Emily Clark (circa 1925) was the youngest daughter of Annie Moysey, a Kurnu Paakantyi matriarch from the Louth area. His stepfather Gilbert Bates was from Yancannia in the Mutawintji area, and his biological father was Mick "Stinger" Hornell, a non-Indigenous man from White Cliffs, NSW. Bates is an elder of the Paakantyi group from the Paaka or Darling River between Wentworth and Bourke. His closest association is with the Kurnu Paakantyi country between Wilcannia and Bourke including the Darling and Warrego River junction, the lower Paroo River, and Mutawintji. He was raised by his extended family, and his main cultural educator was grandmother Granny Moysey, with whom he traveled his country, learning language, history, and culture. At the age of 8, his grandmother began to teach him how to carve emu eggs and make wooden artifacts which later became part of his artistic repertoire.

He worked as an Aboriginal sites officer with the National Parks and Wildlife Service, Broken Hill, NSW, for 22 years (1983–2005) until the age of 59, when he retired to focus on art and his role as a cultural heritage advisor full-time. Badger worked with many Australian archaeologists including Peter Clark and Allen Thorne (Mungo National Park); Dan Witter, Jeanette Hope, Harvey Johnson, and Sarah Martin (National Parks Regional Archaeologists); Colin Pardoe (Lake Victoria project); Ben Gunn (Mutawintji rock art projects); as well as Simon Holdaway and Trish Fanning on the Western NSW Archaeological Project. Badger's cultural knowledge was vital for understanding Australian archaeology particularly, the process for cooking in heat-retainer ovens and eating marrow from kangaroo tail cooked in ashes for which archaeologists began to realize why kangaroo bones were broken into small pieces in some sites. Badger has attended and spoken at many national and international conferences, including ICOMOS and Indigenous Land Conferences where he presented papers in Mutawintji. He continues to campaign for more substantial involvement of Aboriginal people in the management of National Parks and Reserves throughout Western NSW.

Bates is regarded as both a traditional and contemporary Indigenous artist who is well known nationally for his carving and linoprint. Bates works in a variety of media including wood, stone, lino, metal, and found objects and produces themes that include anthropological, archaeological, and political references associated

Bates, William Brian (Badger), Fig. 1 Parntu Thayilana Wiithi – Cod Eating Yabbies, linocut print (2004)

with his cultural attachment to the Darling, Lower Paroo, and Lower Warrego Rivers. His artwork is an extension of Indigenous oral traditions and in his work shares important knowledge about ceremonial and mythological places, traditional lifeways, stories about the ancestral spirits, as well as contemporary issues such as the degradation of the Darling River. As an art educator, Bates has held several roles while teaching linocut, sculpture, and carving including TAFE lecturer at Wilcannia; outback field trip mentor for the College of Fine Arts, University of New South Wales; artist's residency at Wilcannia Arts Community in 2006 and 2007; and mentor for the River Red Gum art project, NSW, in 2011.

Bates has been heavily involved in activism, education, archaeology, native title, cultural heritage management, and water issues in the Murray-Darling Basin. He successfully campaigned on behalf of Indigenous land rights and the protection of significant sites against unacceptable management, spoilage by mining, agricultural practices, and urban expansion. This included the Mutawintji National Park hand back and the recent largest native title claim in NSW for the Barkandji people (Figs. 1, 2, 3, and 4).

Bates, William Brian (Badger), Fig. 2 Stone Sculpture – Stolen Generations Memorial, Mt. Annan, Sydney, 2007

Major Accomplishments

Contributions to Archaeology and Cultural Heritage in NSW

During his extensive period working as an Aboriginal sites officer for the National Parks and Wildlife Service, NSW, for 22 years (1983–2005), Badger was heavily involved in Indigenous cultural heritage management and archaeology within this region. This included ongoing protection and management of many cultural and archaeological sites in Western NSW (i.e., burials and middens at Lake Victoria and

Menindee Lakes; rock art sites at Mutawintji, Sturts Meadows, and Peery; and stone quarries, open sites, and stone arrangements at Tibooburra),

Bates, William Brian (Badger), Fig. 3 Badger at a canoe scar cut out by his grandmother Granny Moysey circa 1922, Wilcannia

and he campaigned against unacceptable management practices and lack of Indigenous involvement at Mutawintji National Park between 1983 and 1998. Badger was also instrumental in the controversial return of "Mungo Girl" from ANU, after the Paakantyi, Ngiyampaa, and Muthi Muthi elders sent him to Canberra to support their case in 1992. Furthermore, he was a cultural educator, providing education and training to archaeologists and other community members about the cultural and spiritual dimensions of archaeological materials and country.

More recently, Bates has been involved with native title and issues related to water management in the Murray-Darling Basin area including the Wentworth to Broken Hill water pipeline for which a statement was released by the Barkandji native title holders on Darling River on 26 July 2017. Badger was involved in nearly 18 years of determinations related to the sixth native title determination in New South Wales and the largest – covering 128,000 square kilometers – from Wentworth at the Victorian border to Wanaaring which includes Broken Hill, Wilcannia, Menindee, Pooncarie, and Dareton.

Selected Art Exhibitions

2010. Museum of Contemporary Art, Sydney, "In The Balance: Art for a Changing World," Badger exhibited three linocut prints as part of a group exhibition.

Bates, William Brian (Badger), Fig. 4 Dandry Gorge Sculpture Connections (2009) featured in Artscape *Sculptures in the Scrub*

2009. "Tin Huts, Grilled Fish & Johnny Cakes," solo exhibition of linocut prints, wooden, metal, and found object sculptures. Mildura Regional Gallery.

2009 and touring till 2012. Objects Gallery and Australian Museum exhibition "Menagerie, Animal Sculptures by Aboriginal and Torres Strait Islander Artists." Badger contributed three sculptures.

2008. "Life on the Darling" exhibition of Badger's linocut prints and sculptures, together with paintings of other Wilcannia artists Phillip Bates, Murray Butcher, and Willy Hunter, Australian Museum, Sydney.

2007. "Bubbles on the Surface II" at Monash University Gippsland Campus, solo exhibition featuring Badger's recent linocut prints and wooden sculptures.

2005. Solo exhibition of 20 linocut prints, Hazelhurst Regional Gallery and Arts Centre, Gymea, Sydney.

2004. "Wilcannia Mission School Kid," inaugural solo exhibition for the opening of the relocated Broken Hill Regional Art Gallery, Sully's Building, featuring linocut prints, wood, and steel sculptures.

2009. "Marella: The Hidden Mission." Badger contributed three linocut prints.

2009. Wilcannia Artists in Residence and Community Artists. Exhibition of the eight artists and community participants of the 3-year program. Broken Hill Regional Art Gallery.

2008. "Bubbles on the Surface III" exhibition, Switchback Gallery, Monash Gippsland, featuring work of Badger Bates and Treahna Hamm, with Daphne Wallace and Chrissie Joy Marshall. Badger contributed 23 works, including linocut and photopolymer prints and embossings, wooden sculptures, and metal sculptures.

2006. New England Regional Art Museum (NERAM) exhibition "Bubbles on the Surface I" with Daphne Wallace, focusing on indigenous artists interpreting their association with water, in this case the Narran River and Narran Lake and the Darling River.

2005. "First People: First State," an exhibition of NSW Indigenous Art, NSW Parliament House, Sydney, with other NSW indigenous artists.

Prizes and Awards

Winner of Outback Art Prize in collaboration with artist Jodi Daley (2015)

Finalist in the Inaugural NSW Indigenous Art Prize in 200.

Murdi Paaki Regional Council Citizen of the Year 200.

Murdi Paaki Regional Council Community Service Award in 1997 for Outstanding Services to Heritage & Culture

NSW National Parks Aboriginal Heritage Achievement Award (1993)

Baths and Bathing, Greek

Monika Trümper
Institute of Classical Archaeology, Freie Universität Berlin, Berlin, Germany

Introduction

Across time and in every culture, bathing is a primal necessity, and the bathing techniques and practices of a culture are revealing for its social concepts, values, and ideas. Thus, the analysis of bathing culture in Greek societies from the Archaic through Hellenistic periods (c. sixth to first century BCE) gives intriguing insights into changing attitudes towards key issues such as cleanliness, purity, leisure, collective pleasure, and enjoyment.

The evidence of Greek bathing culture includes three different sources:

1. Bathing images that are mainly represented on vases from sixth to fifth century BCE Athens and also on some South Italian vases of the fourth century BCE. These images show either nude young women or nude young men washing their entire body at high pedestal basins (*louteria*). Genders are strictly separated in these scenes, but bathing is still performed predominantly collectively, in groups of 2–5 persons. This corpus of bathing images is unique in the ancient Mediterranean world, and in its highly standardized imagery also has no parallel in any later cultures. While many aspects of these images are debated, it is obvious that they served primarily to display perfectly beautiful, well-groomed nude bodies in an intriguing variety of poses and did not faithfully depict contemporary bathing practices and facilities. Even as largely fictional representations, the bathing images were clearly shaped by and in turn reinforced and reflected contemporary social concepts of beauty, body, and gender (Kreilinger 2007; Stähli 2013).
2. Literary, epigraphic, and papyrological texts from different regions of the Mediterranean. Some date to the fifth to first centuries BCE and others come from the Roman Imperial period, but cite earlier authors or clearly refer to earlier periods. While the texts are scanty overall and heterogeneous in date, genre, and provenance and offer no detailed description of a visit to Greek baths, they can be exploited for important information about the reputation, use, and management of baths, as well as related topics such as concepts of cleanliness.
3. Archaeological remains of over 200 bathing facilities from the fifth century BCE onwards that are located across the entire Mediterranean. These remains are by far the most important and conclusive evidence for an assessment of Greek bathing culture and will be the main focus in the following.

Definition

Greek societies washed and bathed regularly for ritual-cultic purification, personal hygiene, and relaxation and recreation. While purifying ablutions and simple cleansing required only cold water and could be performed in natural bodies of water or at simple basins, thorough cleansing and particularly relaxing bathing practices entailed the development of purpose-built bathing facilities, including a sophisticated technology to heat water and spaces. How Greek bathing facilities can be clearly distinguished from that of other ancient Mediterranean cultures (e.g., Etruscan, Punic, Roman) is debated; identification is mainly based on date (above all fifth to first century BCE), context (e.g., Greek city, Greek sanctuary, Greek *gymnasion*), and bathing program (see below).

"Greek" bathing facilities were mainly found in three different contexts:

1. Houses and royal palaces, which provided mostly single rooms for individual bathing and rarely more extended bath suites for collective bathing. Bathing forms employed mainly hot water and occasionally hot air to induce sweating. Comprehensive statistics cannot be provided for this vast category, because standards varied widely between different cities. Thus, while in Olynthos (northern Greece, 432–348 BCE) about 27% of the known 86 houses had their own bathing room, in Delos (Cycladic island, 167/166–69 BCE) this standard was only provided in about 14% of the known 89 houses. In general it is obvious that a private purpose-built room for bathing was always a luxury and never became standard in the Greek world (Trümper 2010).
2. Sports facilities (*gymnasia/palaistrai*) that provided single rooms for collective bathing and sometimes more extended bathing facilities. The default bathing form consisted of simple basins for washing with cold water; these were occasionally complemented by pools for collective cold plunge baths. By contrast, hot bathing was only rarely and tentatively introduced and exclusively in the form of sweat baths. Bathing facilities were most likely a standard of sports facilities, because athletes had to clean themselves after training. However, of the 22 Greek *gymnasia* that are partially or fully excavated, only 13 so far have yielded evidence of bathing facilities (Delorme 1960; von den Hoff 2009; Trümper 2013a).
3. Independent publicly accessible baths ("public" baths, *balaneia*) which offered a broad variety from single to multiple collective bathing facilities, always including bathing forms with hot water and, much more rarely, hot air for sweating. By contrast, cold water was used for washing hands and feet and only exceptionally for immersion baths. While the "public" baths were mostly freestanding buildings, they could also be incorporated in larger building complexes, albeit always as self-contained, independently accessible units. Most of them were built in urban or suburban contexts, with the exception of four examples in extraurban sanctuaries, among them most prominently the sanctuary of Zeus in Olympia. Currently, 70 "public" baths are known from the entire Mediterranean, 39 of which were discovered in the southeastern Mediterranean (Libya, Cyprus, and mostly Egypt), 22 in the northeastern Mediterranean (Turkey, and mostly Greece), and nine in the western Mediterranean (mostly Sicily and South Italy) (Trümper 2006, 2009; Lucore and Trümper 2013).

The "public" baths, built exclusively for the purpose of bathing, offer the best evidence for reconstructing the development and crucial changes of bathing standards. House owners strove to emulate the standards and innovations of "public" bathing culture, whereas bathing facilities in *gymnasia* developed largely independently, obviously for sociocultural reasons. According to literary sources, hot baths had a somewhat dubious reputation, at least in fifth and fourth century BCE Athens, because they would destroy the morals and bodies of bathers, most notably young men, who were supposed to devote their day to exercising in the *gymnasion* instead of to idle chatter in the *balaneion* (especially Aristophanes, *Nubes 1046, 1053–1054;* see also Plutarch, *Demetrius 24.2–3;* Athenaeus, *Deipnosophistae 1.18c;* Trümper 2013b).

Historical Background

Literary sources from the second century CE refer to the existence of *balaneia* ("public" baths) in Sybaris (Greek colony in South Italy) at the end of the sixth century BCE (Athenaeus, *Deipnosophistae* 12.518 c). This may be an anachronism, however, because Sybaris was notorious for its wealth and luxurious lifestyle, of which public hot baths obviously constituted an indispensable part for an author of the Roman Imperial period. The earliest archaeological remains date only to the fifth century BCE. The earliest *balaneion* so far was discovered in Athens

outside the city wall near the Dipylon Gate. It has been dated to the period when the city and particularly its fortifications were rebuilt after the Persian wars (after 480/479 BCE). Slightly later, around 400 BCE, the most famous sanctuary of the Greek world, that of Zeus in Olympia, was provided with its first *balaneion* for the convenience of the visitors (see below). At the end of the fifth century BCE, private bathrooms are testified to in some houses, such as the houses of Olynthos, which were, on average, large and well appointed (Trümper 2010).

When cities and sanctuaries were gradually monumentalized and provided with standard building programs from the fourth century BCE onwards, the number of bathing facilities increased. Thus, ten of the 70 *balaneia* were constructed in the fourth century BCE, in Greece, Asia Minor (Turkey), and a Greek colony in France (Marseille). At the same time, *gymnasia* appeared as monumental edifices with simple cold water bathing facilities (Delorme 1960; von den Hoff 2009; Trümper 2013a).

The revolution of Greek bathing culture occurred in the Hellenistic period (end of fourth century to 31 BCE), however, both in terms of quantity and quality. Thus, most of the known *gymnasia* and particularly 59 of the 70 known *balaneia* were built in this period, in settlements all over the Mediterranean. Furthermore, innovative concepts and standards of bathing were introduced in all different urban-architectural contexts (see below). This agrees well with general sociocultural trends of the Hellenistic period, notably a significant increase in the dissemination and refinement of urban culture; a new focus on individual well-being, pleasure, and luxury; and major advances in the fields of science, technology, as well as architecture and urban planning. While most of the Hellenistic societies were affected by these same trends, distinct bathing practices developed in different regions of the Mediterranean. Three different regions can be discerned: the western, northeastern, and southeastern Mediterranean (Trümper 2006, 2009). Regional diversity was most likely due to different traditions, behaviors, and norms in societies that were now often multiethnic and multicultural. For example, Greek settlers that were invited by the new Greek rulers (Ptolemies, 306–31 BCE) to settle in recently conquered Egypt brought their own bathing practices, and Greek *balaneia* appeared all over Egypt from the third century BCE onwards. According to written sources, indigenous people also frequented these Greek baths and may have had significant impact on the development of an idiosyncratic Graeco-Egyptian bathing culture (see below).

Despite the significant changes in bathing culture from the fifth through first century BCE, the important feature of patronage did not alter during this period. Written sources confirm that *balaneia* were predominantly, if not exclusively, privately owned and managed as profitable business investments (e.g., IG 2^3 84, 418/417 BCE; IG 2^2 2495, 335/334 BCE; ID 98, B, 33–34, 377/376–374/373 BCE; Isaeus, *Dikaiogenes* 22–24; Isaeus, *Philoktemon* 33; for references in Ptolemaic papyri, see Préaux 1947: 44). They did not figure among the standard building tasks of cities, such as political-administrative buildings, theaters, and *gymnasia*, nor were they popular targets for generous donors before the first century BCE. Exceptions were probably the few baths in sanctuaries that were under the responsibility and supervision of the respective administrations (see especially the *diagramma* of Andania, IG 5,1 1390, lines 106–111, 91/90 BCE or first century CE). Thus, the "public" aspect of most *balaneia* refers to their accessibility – publicly accessible for entrance fees – and not to their patronage, ownership, or management. By contrast, *gymnasia*, including their bathing facilities, were commonly financed by the cities and were the preferred objectives of private benefactors from the second century BCE onwards.

Key Issues/Current Debates

Greek bathing culture was first studied comprehensively and masterfully by the French scholar René Ginouvès (1962). Although the archaeological evidence has almost doubled since 1962 and research questions have changed significantly, Greek bathing culture did not receive much

attention, particularly in comparison to the more popular Roman equivalent. Instead, it has long been underestimated in its significance, both for the ancient Greek world and in modern scholarship, notably cultural and sociohistorical studies.

This changed only recently, with the reexamination and excavation of numerous Greek baths (e.g., Caulonia, Locri Epizefiri, Morgantina, and Velia in Italy; Hephaistia, Olympia, Pella, and Thessaloniki in Greece; Buto/Tell el-Fara'in, Euhemeria/Quasr el-Banat, Karnak, Kom el-Khamsin, Krokodilopolis/Medinet el-Fayoum, Schedia, Taposiris Magna/Abusir, and Theadelphia/Kharabet Ihrit in Egypt) and with the first international conference dedicated to this topic, which took place in Rome in 2010 (Lucore and Trümper 2013).

Greek baths are now explored as important evidence of sociocultural concepts, practices, and traditions. A key concern is to carefully reconstruct all bathing practices and standards, their social significance, and the technologies and resources they required. Major emphasis is placed on chronological development and regional differences and the political, social, and cultural factors that may have affected and inspired changes and diversity. This reassessment of Greek bathing culture is based on new excavations that employ modern methods and technologies, a critical reevaluation of old excavations, and extensive cross-cultural studies, notably comparisons with societies whose bathing culture is well known and thus may give crucial insights into the sociocultural complexity and intricate connotations of bathing.

Balaneia ("Public" Baths)

Balaneia in the Northeastern Mediterranean

The development of Greek bathing culture can be demonstrated exemplarily in the sanctuary of Zeus in Olympia, which was provided, from about 400 BCE onwards, with a sequence of *balaneia* that were constantly refurbished and modernized. The first *balaneion* ("Older Sitzbath"), built around 400 BCE, included only one bathing form, notably 11 small hip-bathtubs (or sitz bathtubs) for simple cleansing shower baths (Fig. 1). Warm water was poured over the sitting bather with vessels, either by the bather or by an attendant; the used water was then collected in a hemispherical cavity at the bottom of the

Baths and Bathing, Greek, Fig. 1 Olympia, "Older Sitzbath": plan of the second phase, late fourth century BCE; © Thibaud Fournet. (After Kunze and Schleif 1944: pl. 13)

bathtub and had to be bailed out by hand. While hip-bathtubs were arranged in Olympia along the walls of a rectangular room (II), in other baths round bathing rooms (*tholoi*) predominated. Although the bathing process was performed individually, the lack of walls or screens between bathtubs assured that bathing in a *balaneion* was overall a collective experience. Better preserved baths show that niches were inserted in the walls above bathtubs for storing clothes, bathing utensils, and occasionally oil lamps. Furthermore, bathing rooms were, in general, decorated with waterproof pavements, stucco, and furniture. The Olympian bathroom, probably from the beginning and certainly after a remodeling in the late fourth century BCE, had a cauldron for heating water, which was operated and supplied from an adjacent service courtyard (with water reservoir e). While the function of the large entrance hall (I, with well a) that was taken over from a previous building cannot be safely identified, it may have been used for activities related to bathing (strolling, waiting, light exercise, drinking water supply).

This first bath was replaced by another ("Younger Sitzbath") around 300 BCE (Fig. 2), which provided essentially the same bathing standard as its predecessor, albeit with increased capacity (room III with 20 hip-bathtubs), multifunctional lounges (I, II), and improved service installations. The latter were now located outside the bathing room, but adjacent to it (furnace with boiler in h, water reservoir f) so that hot water was conveniently available through an opening between furnace and bathing room. These key elements – a room with hip-bathtubs and, well separated from this, service facilities for storing and heating water – constituted the standard of all *balaneia* from the fourth century BCE onwards. These baths were simple and mostly functional in design and decoration. Most challenging was the roofing of round rooms, whose interior diameter could be about 11 m (c. 40 hip-bathtubs). In this case, a central support was required, evidence of which in the form of bases was found in several baths (e.g., in Athens: Dipylon Bath, Baths outside the Piraeus and Diochares Gates). Some fourth century BCE baths in Greece, however, had lavish decoration with polychrome figured pebble mosaics in bathrooms or entrance rooms suggesting that this building type had gained in prestige and importance (e.g., Ambrakia; Athens, Bath outside Diochares Gate; Corinth, Centaur Bath; Piraeus, Serangeion Bath). Another innovation of fourth century BCE baths was the

Baths and Bathing, Greek, Fig. 2 Olympia, "Younger Sitzbath": plan, c. 300 BCE; © Thibaud Fournet. (After Kunze and Schleif 1944: pl. 16)

duplication of bathing rooms with hip-bathtubs (mostly two *tholoi*; e.g., Ambrakia; possibly Piraeus, Serangeion Bath), which were most likely designed for use by the different sexes. Written sources testify that women frequented *balaneia* and that gender separation was a major concern. Some papyri from third century BCE Egypt mention a women's *tholos* and possibly also a men's *tholos*, suggesting that baths with double *tholoi* reserved one round bathing room for each of the sexes (Ginouvès 1962: 222–3; Meyer 1992; Trümper 2012). By contrast, if *balaneia* with single bathing rooms were used by both sexes, gender separation could only have been achieved through different bathing hours.

The simple functional *balaneion*, introduced in the fifth century BCE at the latest and consolidated and partially refined in the fourth century BCE, was continuously used through the first century BCE and in some regions even beyond that date. At the same time, a significant change in bathing standards occurred in the Hellenistic period, from the third century BCE onwards, with the introduction of new relaxing bathing forms. Cross-cultural studies on bathing clearly show that two criteria are considered as standard for relaxing bathing: heat and time. This means that a certain amount of time has to be spent in a comfortably warm or even hot environment that consists commonly of water, dry heat, or steam. All relaxing bathing forms also have a physically cleansing component, through the use of water or sweating. Relaxing bathing forms are thus not a real antipode to merely cleansing ones, but include and thereby substitute for them. In Greek bathing culture, the new relaxing bathing forms entailed and required advanced technology, increased monetary expense, and, above all, a collective societal endorsement of leisure, pleasure, and indulgence. They would most likely have enticed people to extend their visits to the baths and would have increased the importance of bathing as a social event.

To return to Olympia, shortly before its abandonment in the first quarter of the second century BCE, the "Younger Sitzbath" was provided with such a new relaxing bathing form, whose nature cannot be safely determined, but which was heated with hot air that circulated in a subterranean channel (hypocaust system) (Fig. 3: IV, i, supplied by new water reservoir g). The successor of this bath ("Late Hellenistic Bath"), built in the second half of the second century BCE, incorporated fully developed modern standards (Fig. 4): a – still predominant – *tholos* with 13 hip-bathtubs (a), two large bathtubs for individual relaxing immersion baths in hot water (c), and a small round room for collective sweat bathing in hot air (b). The two new bathing forms were heated by a sophisticated hypocaust system (e) that also provided hot water for the hip-bathtubs.

Several other baths in Greece offered a similarly complex bathing program, among them the fully excavated example in the sanctuary of Asklepios in Gortys (Peloponnesus) (Ginouvès 1959) (Fig. 5). Although this bath was, probably in the second century BCE, inserted into a preexisting building with a different function, its design represents key elements of the new standard: a clear separation of bathing (A–F, V) and service (W–Z) sections; a lavish colonnaded entrance (*propylon* A); a *tholos* (G) with nine hip-bathtubs; a room (D) with three individual immersion bathtubs; a small round collective sweat bath for about four bathers (E); several multifunctional lounges and a distributive room with benches and various cold water basins (B, C with basins θ and λ, H); a fully developed hypocaust system with a ring-shaped channel for heating water, the relaxing bathing forms and parts of two lounges (B, C); and finally double entrances to the bathing section (A and I, both with statue bases π and ρ; third service entrance to room W) for differentiated use. The archaeological evidence even suggests that bathers could not pass over the hypocaust system (Y) from the distributive room C to the *tholos* G; thus, the two bathing sections were probably entirely independent, just using a common heating system (Y). The nature of this differentiated use cannot be safely determined, but the different circulation patterns may have provided the option to choose between a quick cheaper merely cleansing bath (G–I) versus an extended costlier stay in the relaxing section (A–F, V).

Baths and Bathing, Greek, Fig. 4 Olympia, "Late Hellenistic Bath": plan, second half of second century BCE; © Thibaud Fournet. (After Sinn et al. 2003: 619, Figs. 4–5)

While this bath is located in an urban or suburban sanctuary of the healing god Asklepios, it did not necessarily serve as a specific medical-therapeutic facility. Water was not supplied by a particular mineral spring, and the bathing program has parallels in urban-secular baths. Despite major progress of medicine in the Hellenistic period, neither medical texts nor the archaeological remains of other Asklepios sanctuaries reveal a particular concern with the development of specific therapeutic bathing practices (Flemming 2013). Similarly, general ritual purifying bathing did not require sophisticated *balaneia* with hot bathing forms, but

Baths and Bathing, Greek, Fig. 5 Gortys, Bath in the Sanctuary of Asklepios: plan, c. second century BCE; © Thibaud Fournet. (After Ginouvès1959: 165, Fig. 187)

consisted mainly of washing parts of the body (hands, head, and feet) at simple basins with cold water. Therefore, *balaneia* in sanctuaries most likely granted visitors the same cleansing and relaxing bathing experience and convenience as their equivalents in urban-secular contexts (Trümper 2013b).

In the northeastern Mediterranean, the complex refined bath type and its simpler equivalent were used well into the first centuries BCE and CE and then gradually replaced by new bathing standards, notably Roman baths. The sanctuary in Olympia was again among the first sites in Greece to be provided with a fashionable Roman-type bath around 40 BCE ("Greek Hypocaust Bath"). This bath no longer included a cleansing section with hip-bathtubs, but only a large pool for collective relaxing immersion baths in hot water (see below). This pool, as well as the entire bathing room, was now heated by a modern hypocaust system with brick pillars.

Balaneia in the Western Mediterranean

New bathing standards were also introduced in other regions of the Mediterranean in the Hellenistic period, albeit with noticeable differences. The most sophisticated and advanced bathing culture was developed in the western Mediterranean, notably Sicily and South Italy. Most of the nine known baths in this region were built in the mid-third century BCE and abandoned around 200 BCE and included two distinct sections, spatially and conceptually clearly separated. For example, the well-preserved *balaneion* in the Agora of Megara Hyblaea (Sicily) (Fig. 6) had a cleansing section with traditional *tholos* (k, c. 20 hip-bathtubs), two multifunctional rooms with benches (l, m), an entrance from the adjacent street (o?), and a large bottle-shaped furnace for heating water (j). By contrast, the much larger and better appointed relaxing section had its own entrance on the Agora (a), a series of multifunctional

Baths and Bathing, Greek, Fig. 6 Megara Hyblaea, Bath in the Agora: plan, c. mid-third century BCE; © Thibaud Fournet. (After Vallet et al. 1983: 51, Fig. 37)

rooms with (c, d) or without (e, f) benches, and a large bathing room (g) with a bench and a collective immersion pool (h). The latter was heated by its own hypocaust channel to keep the water warm. This large collective heated immersion pool differs significantly from the individual immersion bathtubs in northeastern baths; not only was its construction, operation, and maintenance far more costly, but it promoted above all a truly collective bathing experience, requiring bathers to use the same water and to face potential physical contact.

Both the cleansing and the relaxing sections in the *balaneion* of Megara Hyblaea were served by the same conveniently located service facilities (service courtyard p, well room q). While the central distributive room of the relaxing section (d) also had an access to the bottle-shaped furnace (j), probably for drawing warm water for various basins (in rooms d and g), room j was most likely completely filled by installations for heating water and thus could not be crossed in order to proceed from the relaxing to the cleansing section, and vice versa (cf. the similar situation in the bath of Gortys, see above). Hierarchy was clearly established by size, accessibility, and decoration, both within each section and between the sections. Thus, while all bathing rooms were provided with waterproof mortar pavements, only some of these pavements were decorated with small stone or marble pieces: room g with the immersion pool received the most intricate decoration pattern, followed by room d and *tholos* k, then room f, then room c, and finally, at the bottom of the decoration scale, rooms e, i, l, and m which had simple mortar pavements without any decoration.

It is obvious that the heating systems of these western Greek baths were more advanced than those of their northeastern equivalents, but the precise reconstruction and functioning of the furnaces and hypocaust systems is currently still much debated (Lucore 2013). The large bottle-shaped furnaces may have held large water basins or a series of juxtaposed (metal) cauldrons, heated by hot air from below; the immersion pools may have been supplied by their own hot water boiler or by innovative intricate devices such as a "tortoise" (*testudo*). The latter, so far only known from Roman baths and authors, consisted of a semicylindrical metal container that was situated over the fire in the furnace, on a slightly lower

level than the bottom of the immersion pool. This container was closed at one end and open at the other, towards the immersion pool so that water could circulate constantly between the pool and the hot tortoise and thus be kept warm.

Other groundbreaking technologies were used in and maybe even developed for western Greek baths, most notably vaulting techniques. In the North Baths at Morgantina, the *tholoi* with hip-bathtubs and two rectangular bathing rooms were covered with a dome (diameter 5.75 m) and barrel vaults (spans of 5.00 and 5.00 m), respectively (Lucore 2009, 2013). These vaults were made of interlocking hollow terracotta tubes that were covered with a rough mortar on both sides and on the interior with additional painted plaster. Apart from the stunning aesthetic effect that these innovative vaults must have had on viewers, domed and vaulted roofs also had practical advantages: heat would have spread more evenly and condensation would not have dripped from the ceiling, but run along the curved walls. In the long run, the advance of vaulting techniques that was closely connected to the development of both Greek and, above all, Roman baths would allow the spanning of ever larger, impressive spaces.

Why the patrons and builders of western Greek baths pressed so much ahead in the development of the designs and related technologies of baths in comparison to their peers in the eastern Mediterranean, cannot be safely determined. Western Greek cities prospered in the third century BCE and were centers of inventions in the arts and sciences. This favorable, stimulating cultural and historical climate may well have had an impact on the promotion of the local bathing culture (Lucore 2009).

The western Greek baths shared significant characteristics with early Roman baths, which developed in the early second century BCE at the latest and are currently known from some 17 cities in Italy, France, and Spain. These early Roman baths commonly included only one or two multifunctional entrance rooms or lounges for activities related to bathing (*apodyterium*, *tepidarium*) and a single bathing room with a collective heated immersion pool (*caldarium*) (Tsiolis 2013). Thus, the crucial difference between western Greek and early Roman baths is that the latter entirely abandoned the separate cleansing section with hip-bathtubs.

Currently, the evidence of western Greek baths and early Roman baths is strangely distributed: no city has yielded clear evidence of both a Greek bath and an early Roman bath (second or early first century BCE), with the possible exception of Pompeii. Indeed, the famous Stabian Bath in Pompeii has often been identified as a Greek bath that was transformed into a Roman bath in the second century BCE, but the complex history of this building is much debated and requires critical reassessment. Another recently excavated example, the bath of Fregellae (Latin colony southeast of Rome, 328–125 BCE), provided evidence of two phases (Tsiolis 2013). The bath of the second phase, dated to the early second century BCE, was clearly Roman, but the predecessor from the late third century BCE cannot be fully reconstructed. While it certainly contained a relaxing section with a heated collective immersion pool, the existence of a separate cleansing section cannot be fully excluded – the more so because remains of a bottle-shaped furnace, a characteristic feature of the cleansing section in western Greek baths, have recently been uncovered.

Therefore, the intriguing relationship between Greek and Roman baths cannot yet be fully assessed and reconstructed. It seems only obvious that the western Mediterranean was the "think tank" of bathing culture in the decades around 200 BCE and very much influenced its development in future centuries. Greek baths may have anticipated their Roman equivalents for a short period in the crucial advancement of bathing culture, notably in the development of both collective leisure bathing as a sociocultural concept and the appropriate technological requirements. Alternatively, these innovative features could have been developed simultaneously in different settings, with two different results, notably the rather short-lived western Greek cleansing and relaxing bath type and the more successful early Roman relaxing bath type, which was maintained and refined in the following centuries.

Balaneia in the Southeastern Mediterranean

In contrast to the bathing culture in the northeastern and western Mediterranean, that of the southeastern Mediterranean was more conservative and austere. In southeastern *balaneia*, hip-bathtubs were, from the second century and probably already third century BCE onwards, only complemented by individual immersion bathtubs that were not heated by a hypocaust system, but simply filled with hot water. Arranged mostly in separate rooms in groups of 2–6, the immersion bathtubs were always far outnumbered by the hip-bathtubs, suggesting that cleansing bathing always prevailed (Fig. 7: 1–2, 7). While in about half of all *balaneia*, rooms with hip-bathtubs were duplicated, this almost never occurred for rooms with immersion bathtubs. Thus, relaxing bathing was clearly reserved for a few privileged bathers and possibly even for one of the sexes, notably the male. The *tholos* or *tholoi* commonly constituted the center and focus of the *balaneia* and were surrounded by extended corridor systems and secondary (bathing or service) rooms. Idiosyncratic to southeastern baths, these corridors certainly

Baths and Bathing, Greek, Fig. 7 Taposiris Magna/Abusir, Bath: plan of the second phase, c. 100 BCE; © Thibaud Fournet & Bérangère Redon. (Fournet and Redon 2013: 245, Fig. 6)

facilitated circulation but may also have served for strolling and as a substitute for multifunctional lounges that were mostly missing in these baths.

Recent research on the Hellenistic bath of Taposiris Magna (northern coast of Egypt, west of Alexandria; Fig. 7) has shown that heating systems of southeastern baths could be far more complex and sophisticated than hitherto assumed (Fournet and Redon 2009, 2013). This bath was partially cut into the rock (rooms 1–5, 10, northern part of room 7) and is therefore exceptionally well preserved. Its heating system (3bis), however, refined in a second phase around 100 BCE, was built in front of the rock-cut parts, close to the *tholoi* with hip-bathtubs (1, 2). While the circular furnace served primarily to heat water for the bathtubs, it also heated adjacent spaces through openings (3) and a heating wall (7). The latter is similar to the wall heating systems of Roman baths, where hot air circulated in "hollow walls." Made of large tiles, the heating wall in Taposiris Magna heated the small relaxation section of the bath (7).

Some southeastern *balaneia* were modernized under Roman rule (after 30 BCE) by transforming *tholoi* into sweat baths or constructing collective cold or hot water pools, but the Greek bathing concept was still astonishingly long-lasting. Thus, Greek baths, with a clear focus on simple cleansing hip-bathtubs, were still used and even constructed in the second century CE, and Roman bathing customs were overall only reluctantly introduced and accepted. This may be one of the reasons why Egypt has yielded more evidence of Greek baths than any other region in the Mediterranean and why the Egyptian baths show significantly more traces of constant repairs and remodeling than their equivalents in other regions. Remarkable also is the distribution of baths which clearly reflects the enormous popularity of public bathing in this country. Thus, even small settlements (e. g., Euhemeria/Quasr el-Banat, Theadelphia/Kharabet Ihrit) were provided with two large public baths, and large cities with an even denser network of such establishments (e.g., in both Buto/Tell el-Fara'in and Krokodilopolis/Medinet el-Fayoum four public baths were found so far).

Sports Facilities *(Gymnasia/Palaistrai)*

While bathing facilities of sports facilities remained largely simple and ascetic for the above-mentioned sociocultural reasons, even they were affected by the dramatic evolution of bathing culture in the Hellenistic period, albeit to a different degree than the *balaneia*. The default athletic bathing form, notably simple bathing rooms with basins for cold water ablutions (*loutron/loutra*), was continuously built and used from the fourth through the first century BCE. Epigraphic sources show that these *loutra* enjoyed a certain popularity and prestige because generous donors paid for their construction and refurbishment from the second century BCE onwards. For example, according to inscriptions, the bathing facilities of the *gymnasion* in Pergamon (Asia Minor/Turkey, capital of the Attalid kingdom), built in the first half of the second century BCE at the expense of King Eumenes II, were improved several times by well-known local citizens, notably in the late second century BCE and again in the mid-first century BCE. Although the building is fully excavated, these improvements cannot be safely identified in the archaeological record, however, and they seem not to have changed the general bathing standard (Trümper 2013a).

In some other *gymnasia*, however, the austere *loutra* were either supplemented or even substituted by extravagant facilities for collective sweat bathing in hot air in the second century BCE. These consisted either of rectangular rooms with barrel vaults (Delos, "Sea Palaestra," and "Gymnasium") or of large round rooms (diameters of 5.90–10.20 m: Assos in Asia Minor/Turkey, Eretria and Thera in Greece, Solunto and possibly Akrai in Sicily) (Trümper 2008: 250–75, 2013a). For example, the *gymnasion* of Eretria (Euboea/Greece, Fig. 8) was built at the end of the fourth century BCE with a simple *loutron* (B) and remodeled in the second half of the second century BCE to include a large round sweat bath (G). These round rooms are well known and were much debated for a long time, and only recent research has ascertained that both the challenging roofing (with conic or domed roofs) and the heating (most likely with hot stones or braziers) could be realistically accomplished.

Baths and Bathing, Greek, Fig. 8 Eretria, Gymnasion: phase plan; phase 1 end of fourth century BCE, phase 2 second half of second century BCE; Mango 2003: 56, Fig. 58

While these various sweat baths must already have revolutionized the experience and concept of athletic bathing, the most significant change occurred only from the late first century BCE onwards when independent sophisticated Roman baths were built in or next to Greek *gymnasia* and hot water was used for the first time in the Greek athletic context. For example, the *gymnasion* of Pergamon was provided with a Roman bath ("West Bath") in the first century CE and a second larger equivalent ("East Bath") in the second century CE (Trümper 2013a). Consequently, in Asia Minor (Turkey) the formerly two distinct concepts – Roman bath and Greek *gymnasion* – were merged into a new building type in the first and second centuries CE, the so-called Bath-Gymnasia. This granted the survival of the Greek *gymnasion* by simultaneously accommodating a dramatically changed concept and perception of bathing.

Future Directions

Since research on Greek baths and bathing culture has only been revived in the last 10–15 years, many of the issues addressed here still require more in-depth analysis. Most important is the full publication of recent and ongoing excavations of both Greek *balaneia* in the different regions of the Mediterranean and early Roman baths in the western Mediterranean. This will provide crucial new insights into important aspects such as the often

neglected and little known history of baths (date of construction, remodeling phases, and abandonment); heating and vaulting technologies; water management, particularly water supply, which is so far poorly understood, especially with regard to quantity and consistency or seasonal variances as well as distribution within the baths; circulation patterns and user differentiation; and the urban context of baths that is often insufficiently known.

Based on such comprehensive fundamental research, broader synthetic questions could be reassessed, most notably the possible sociohistorical reasons for obvious regional differences in bathing culture, including the complex interrelation and transition between Greek and Roman bathing customs.

While the bathing images on vases have been much studied in recent years (Kreilinger 2007; Stähli 2013), a comprehensive assessment of all written sources related to bathing in the Greek world is still missing.

A reassessment of all different sources – images, texts, and archaeological remains – could finally result in a more differentiated comparative evaluation of the discourses on Greek bathing culture in the various media. Greek bathing culture could then finally receive the attention it deserves, both in interdisciplinary studies of the ancient Mediterranean world and in cross-cultural studies on bathing and related topics.

Further Reading

An overview of recent and current research is available in the proceedings of the recent conference on *Greek Baths and Bathing Culture. New Discoveries and Approaches* (Lucore and Trümper 2013). The 14 English contributions include summaries of recent and ongoing fieldwork (Caulonia, Fregellae, Locri Epizefiri, Monte Iato, Morgantina, and Velia in Italy; Hephaistia/Lemnos and Thessaloniki in Greece; Euhemeria/Qasr el-Banat, Taposiris Magna/Abusir, and Theadelphia/Kharabet Ihrit in Egypt) as well as synthetic assessments of topics such as bathing images; bathing in Greek medicine; heating systems; vaulting systems, also in relation to contemporary science (Archimedes); urban context of Greek public baths; and the relationship between Greek and Roman baths. The second part of this book consists of a catalog of all currently known Greek *balaneia* (for each bath: short catalog text, bibliography, standardized plan).

This topic is currently not conveniently and easily accessible in recent English handbooks or textbooks. The standard handbook is still Ginouvès 1962 (in French), which is excellent, but partially outdated for the assessment of bathing images and the archaeological evidence of baths.

Baths and Bathing, Roman

Matthew McCallum
Department of Archaeology, Conservation and History, The University of Oslo, Oslo, Norway

Introduction

Public baths were arguably the primary social institution of the Roman world. A trip to the local public bath was both a practical and pleasurable ritual, fundamental to the routine of daily life – we have evidence of everyone from slaves to the emperor himself frequenting the public baths on occasion. Many baths also catered for experiences well beyond that of simply getting clean; bathers could spend several hours in the baths, socializing or attending to a multitude of other needs and desires.

The baths were at the forefront of Roman architectural, engineering, and design development. The forms expressed in the bath buildings, along with their materials and technologies, were among the most innovative, ambitious, and impressive of their day and have remained influential through to modern times. Public baths were a ubiquitous feature of most cities and towns, irrespective of size, as well as in many sanctuaries and military camps; they became a defining feature of Roman civilization throughout the Empire and beyond.

Sources and Reception

It is obvious from the sheer number of baths alone (see section "Types of Bathing Facilities") that the

act of public bathing was extremely popular, and their centrality to daily life is confirmed by the fact that references to bathing are to be found everywhere, including in official inscriptions, on informal graffiti, in school books, on tombstones, and of course in the literary sources, where they are frequently mentioned by poets (most notably Martial), historians, philosophers, and the like.

The sources make frequent references to positive aspects of the baths, including their grandeur, beauty, atmosphere, and social and medical benefits. However, as to be expected with any popular institution, they were not universally praised and we do hear the occasional dissenting voice. Gripes with the baths ranged from annoyance at the drunken, lecherous, licentious, sycophantic, or arrogant behavior of some regular visitors, to instances of theft (a common issue at the baths, subject to strict laws, and, if the laws did not work, curse tablets [Fagan 1999: 36–38]), to the water being too dirty, cold, or hot (Nielsen 1990: 18; Fagan 1999: 181–186). There were also moral objections to the popularity of the baths, with several commentators raising concerns about the negative effects on society of the perceived indulgences and luxuries offered at the baths (Seneca Letters 86 is one such lament). These objections, though eloquent, would appear to be the viewpoint of a conservative minority, and even their objections were not serious enough, in most cases, to stop the critics themselves from frequenting the baths, further highlighting their importance as a social and cultural hub.

Definition

The Roman public bathhouse in its many contexts may be distinguished from earlier forms of public bathing (see the entry on "▶ Baths and Bathing, Greek", in this encyclopedia) and defined by the existence of three primary characteristics: (1) a complex heating system based around the hypocaust, (2) bathing rooms of differing temperatures, and (3) the presence of communal pools. While some of these elements could be present in the earlier "Greek-style" baths (with which the Roman baths had many aspects in common – see section "Historical Background"), it is the combination of these elements that epitomizes the Roman style of public bathing regardless of context.

Heating

A Roman bath was heated by the hypocaust; an underfloor system of heating that was fully developed by the early second century BCE. Prior to this time, heating of rooms and water tended to be carried out with the use of braziers or on occasion by simpler forms of underfloor heating (see section "Historical Background" and the entry on "▶ Baths and Bathing, Greek", in this encyclopedia). The hypocaust functioned by allowing hot air and gasses to flow through a space created beneath the floor of a room (Fig. 1). The most common way to create this space was to raise the floor via the use of multiple square or circular brick columns (*pilae*), typically standing between c. 0.70–1.40 m in height, and placed roughly 0.80 m apart from center to center. Resting on the *pilae* was the floor matrix, usually consisting of large square tiles (*bipedales*), upon which was laid a 0.30–0.40-m-thick brick and mortar packing into which the desired surface material was laid.

The heat was generated by a simple, slow-burning furnace (*praefurnium*), consisting of a fire placed in one or more openings in the external wall below the floor of the heated room (Fig. 1). Two spur walls (not pictured) were often built either side of this opening (and either side of the wall) to help draw the hot air and gasses through the system. The hot air and gasses eventually rose up through flues set into the wall and exited the system via vents set just below the eaves of the building (see also "tubulation" below). As to be expected, there were many design variations with the hypocaust system, not least with the *pilae*. One such variation – and a notable example of ancient recycling – is still to be seen in Athens, with the reuse of 17 Hellenistic period columnar grave monuments as *pilae*.

Service areas were invariably situated outside these heated rooms. Depending on the size or build of the bath, these areas could vary from simple semi-open spaces (usually with some

Baths and Bathing, Roman, Fig. 1 The heating system of a Roman bath (modelled on the *caldarium* of the Central Baths in Pompeii). (Image: Jean-Pierre Adam (2011), with permission)

form of screening to hide the work areas from the public) through to a complex network of underground passages (such as those at the Baths of Caracalla in Rome). It was from these services areas that the water supply for the baths was also controlled. The water to be used in the heated pools was piped into large metal boilers that were often sensibly positioned above the furnace (Fig. 2). Once heated by the boiler, the water could be mixed with cold water (as required) by the service attendants as it was being piped into the pools: a particularly well-preserved example of a water-supply system was found in a villa at Boscoreale, a settlement buried in 79 CE by the same eruption of Mt. Vesuvius that destroyed Pompeii and Herculaneum. Some baths also incorporated a semicylindrical metal container known as the *testudo* into their water-heating systems (Fig. 2). The closed end of this device was placed above the furnace in direct contact with the fire, while the open end was incorporated into the sidewall of the pool. This configuration allowed the pool water to circulate directly above the furnace, thereby maintaining a much warmer water temperature for the bathers.

From the first century BCE onwards, it became common to create hollow passages in the walls of the heated rooms (beyond the basic, but necessary flue system), in a technique known as tubulation. This provided several structural and functional benefits: it allowed for the improved circulation and extraction of hot air and gasses; it provided the walls with dry lining, thereby alleviating dampness in such a hot and humid environment; and it led to a more efficient use of fuel through the effects of radiant heat contributing to a higher room temperature while simultaneously allowing for a more uniform and safer temperature for the floors and the walls – an important concern for the patrons (Nielsen 1990: 17–8; Yegül and Couch

Baths and Bathing, Roman, Fig. 2 Reconstruction of the heating and water systems of a *caldarium*, including boiler and *testudo*. (© Koninklijke Brill NV (after Manderscheid 2000: 496))

2003: 175; Schiebold 2006; Yegül 2010: 88–9). The radiant heat generated by tubulation also allowed for larger heated rooms to be built and for these rooms to be well lit, because large windows could now be placed in the walls of heated rooms without the loss of too much temperature. The interplay between the sun and the variously decorated surfaces of the baths, coupled with the potential for pleasant views, added to the spectacle of a visit to the baths. As Seneca colorfully informs us (*Letters* 86.8), well-lit baths were popular among patrons.

Tubulation appeared in several forms and subtypes, varying over time and region, but two forms, *tegulae mammatae* and *tubuli*, were by far the most commonly utilized throughout the Empire (Fig. 3). *Tegulae mammatae*, literally "tiles with nipples," consisted of specially constructed flat tiles with projecting studs on each corner that were attached to the wall with metal clamps. *Tubuli* were custom-made hollow box-shaped tiles, open at both ends and often on the sides. These could be stacked on top of, and next to, each other to create an interconnecting network. *Tubuli* are considered to have been the most effective method for heating, as the air and gasses circulated through *tubuli* with less turbulence than with other solutions (Adam 1994: 269). They also had the added benefit of not necessarily requiring the use of costly, and ultimately ephemeral, metal clamps to attach them to the wall, thus saving on both materials and effort while also extending the life of the building. The use of *tubuli* essentially superseded *tegulae mammatae* in many parts of the Empire from the end of the first century CE onwards. However, the continued use of *tegulae mammatae* would seem to be a trend throughout Greece and in parts of the Western Empire (Nielsen 1990: 15, 1999: 36; McCallum 2010). There are also many examples of more than one type being utilized within the same building, as was the case in the Great Bath at Corinth where three different systems have been observed (Biers 2003: 310). Tubulation was also utilized in some bath ceilings, providing further insulation and structural benefits, including in the thermal baths at *Aquae Sulis* (Bath, England).

When taking into account that the floor, walls, ceilings, pools, and water boilers were all heated by the same furnace, in effect every element of a room could be heated from a single source of fire under the floor – an ingenious and very efficient system.

Variated Temperatures

Not only did the Romans heat certain rooms of the baths, but they also manipulated the temperatures

Baths and Bathing, Roman, Fig. 3 Detail of a diagram showing (**a**) tegulae mammatae (**b**) tubuli. (© Fikret Yegül (after Yegül 2010: 88, Fig. 38))

of these rooms and their waters to provide a variated experience for the bather as they moved from room to room. Consequently, the three fundamental room types experienced when taking a Roman bath were the cold bathing room (*frigidarium*), the warm room (*tepidarium*), and the hot bathing room (*caldarium*). Many baths also included a dedicated sweat room, referred to variously as a *sudatorium* or *laconicum*. Depending on the establishment this could be based around a wet heat or a dry heat.

Communal Pools

The physical process of bathing in a Roman bathhouse took place primarily in communal, fully immersible pools, often large enough for several people to bath simultaneously. Typically two or more pools were present in both the *frigidarium* and the *caldarium*; the *tepidarium* often functioned as a heat lock between the cold and hot rooms, although pools are present on occasion. In addition to communal pools, many baths (especially down to the first century CE) also featured a pedestalled washbasin (*labrum* –). This piece of bathing furniture had a long history in public bathing, from at least the Greek Archaic period onwards. Also extremely popular in Roman baths (and some earlier Greek gymnasia) were large swimming pools (*natatio*); these could be indoor or outdoor, heated or unheated, depending on the climate and the establishment.

Auxiliary Rooms

Aside from the rooms devoted to the actual act of bathing, public baths, regardless of size, also regularly included a dedicated changing room (*apodyterium*) with niches for the bather's clothes and personal effects as well as oiling rooms, latrines, and, depending on time and place, a courtyard and/or a large all-purpose indoor room for light exercise or socializing. Some baths even featured facilities for massage and sunbathing, as well as shops, mills, offices, large garden areas, running tracks, fountains, and cult spaces (typically of the Imperial family or Mithraea), with the largest baths even including further educational and entertainment zones such as libraries, lecture halls, class rooms, and eclectic art galleries (for a discussion of the individual elements of the baths, see Nielsen 1990: Appendix). The patronage and display of sculptural art in the bathhouses presented the Imperial family, local administrators, athletic clubs, and other personages and institutions of note a wonderful opportunity to honor gods and mortals while increasing their own status and reputation. Public baths regularly provide us with impressive examples of Roman art, along with copies of Greek sculpture and even pilfered Greek originals.

The written sources inform us that the rooms of the baths were also home to more ephemeral services and entertainments (professional and otherwise): food and drink sellers, depilators, poets, jugglers, musicians, dancers, mimes, and even

male and female prostitutes are all known to have added to the bathing experience. One of the liveliest descriptions of the atmosphere in a small bath is from Seneca, who in the mid-first century CE complains of the noise made by people enjoying themselves or making a living at the baths (*Letters* 56.1-2). With so much available space and so many facilities on hand, some of the largest baths even became regular places of assembly for events and political gatherings, thereby taking on some of the roles traditionally reserved for the forum.

Bathing Pattern

There appears to have been no universal set pattern to how one would experience the baths; they vary tremendously in layout and features (as to be expected over such an immense chronological and geographical expanse), suggesting that, in essence, the baths could be approached how the individual bathers themselves desired. Furthermore, very few surviving sources describe in any great depth and clarity what was to them an everyday process. Undoubtedly, force of habit and the inherent restrictions imposed by the layout of the individual bathhouse would have played a role, as would have contemporary medical advice. One way to approach the bathing process would be to pay the fee (if there happened to be one at that particular establishment), get changed in the *apodyterium*, oil up, then work up a sweat (via light exercise or a dedicated sweating room), before finally entering the bathing rooms proper (perhaps most often in the basic order of *tepidarium*, *caldarium*, *frigidarium*), where first the oil, sweat, and potential dirt could be scraped off with a *strigil* (– soap was not widely used in the Roman Empire) and then one could enjoy a dip in the various plunge pools or even a swimming pool. A hefty dose of socializing and the enjoyment of any of the other delights on offer would supplement this process. Eventually the bather would return to the *apodyterium* to get changed and exit the establishment.

Types of Bathing Facilities

The widespread popularity and long history of the baths meant that many types of bathing establishment existed throughout the Empire. The two most basic types were freestanding baths and bathing facilities attached to larger complexes. There was of course a lot of variation within these two basic types.

B

Freestanding Bathhouses

The most common type of public bathing establishment throughout the Empire was the freestanding bathhouse, dedicated primarily to the act of bathing and socializing for groups of people. They varied greatly in size and accessibility (see Key Issues). The ubiquitous, smaller freestanding establishments are commonly referred to as *balnea*, while the larger and more imposing baths tend to be referred to as *thermae*. The interchangeability of these terms, and indeed many of the terms related to the baths in ancient times, still causes problems today (see Nielsen 1990: 3, Appendix; DeLaine 1993: 352–4; Fagan 1999: 14–9 with further references).

Balnea were often privately owned and varied greatly in layout and size, with some very innovative and unique design variations – in part caused by the necessity of fitting into preexisting town plans and the lay of a particular plot of land. Thermae tended to be state- or city-run enterprises; they were often more symmetrical in design and layout but were nevertheless among the most innovatively designed and decorated buildings to be found in a city of the Empire. In Rome alone, during the fourth century CE, census documents record that an incredible 856 small baths and some 10 or 11 massive thermae were in use (the exact number varies for both categories – *Notitia Urbis Regionum* and *Curiosum Urbis Romae* Regionum; Fagan 1999: 41–2; Yegül 2010: 2–3). Agrippa constructed the first thermae in the city of Rome during the last quarter of the first century BCE, and then we know of increasingly more elaborate and monumental thermae constructed by leading citizens and emperors, including (but not limited to) Nero, Titus, Domitian, Trajan, Commodus, Septimius Severus, Caracalla, Decius, Diocletian (the largest of the Roman Imperial thermae), Maxentius, and Constantine. Many other major cities also

featured at least one thermae, including, but by no means limited to, Constantinople, with at least 8 thermae and 153 small baths (*Notitia Urbis Constantinopolitanae*; Yegül 2010: 3, 183), Carthage, Ephesus, Antioch, Lepcis Magna, Paris, Trier and Athens, with at least 2 thermae and over 50 small baths of various types (McCallum 2010). Even Ostia, the port of Rome, has seen several thermae and over 20 smaller baths uncovered during excavations (Yegül 2010: 69).

Bathhouses Attached to Larger Complexes

Bathing facilities were also regularly constructed as an element of much larger complexes, including gymnasia, military forts, sanctuaries, thermo-mineral resorts, domestic dwellings, and even churches.

Gymnasia

In those parts of the Empire where the gymnasium was an important cultural institution, notably in Greece and the Hellenized East, the tradition continued of incorporating bathing facilities to assist with cleaning after exercise (a practical tradition considering their exercise regime combined dirt, sweat, and oil), the difference being that during the first centuries of the Empire, most were outfitted with the latest in Roman heating technologies (see the entry "▶ Baths and Bathing, Greek", in this encyclopedia).

Conversely, many standard freestanding Roman baths incorporated some elements of the gymnasium into their design, most notably with the appearance of a small courtyard for light exercise, but it is with the great bath-gymnasium complexes of Asia Minor that we see the truest fusion of the features and activities of the Roman bath and the Greek gymnasium. Some of the most notable examples of this phenomenon are preserved at Ephesus (Harbour Bath-Gymnasium, Vedius Bath-Gymnasium, East Bath-Gymnasium, Theatre Baths), Sardis (Imperial Bath-Gymnasium – Fig. 4), Perge (South Gate Baths), and Miletus (Bath-Gymnasium of Faustina).

Military Baths

Wherever Romans went, so went the baths. As a result, baths were a regular feature of military forts (*castrum/castra*) around the outskirts of the Empire. These baths can be divided into two categories: large legionary thermae, typically located inside the fortress, and smaller *castellum* baths, which lay outside of the fort (Nielsen 1990: 77). The baths were designed by the military architects that accompanied the army, and it was these same architects who were often responsible for designing and constructing the baths in the newly conquered, assimilated, or created settlements at the frontiers of the Empire. As a result, we see in places like Roman Britain that the settlement baths regularly share design similarities with the baths from nearby military forts.

The Roman military can thus be seen as an important contributor to the spread of baths throughout the provinces of the Empire, with the baths themselves playing a significant role in the complex process of sociopolitical and cultural interaction and domination known as Romanization.

Sanctuary and Thermo-mineral Baths

Any place where large crowds of people would be gathering or staying for an extended period benefitted from having public baths, and this was certainly the situation at sanctuaries where devotees congregated for days or even weeks at a time, be it for festivals (athletic or otherwise) or for healing. Baths were an integral part of many healing sanctuaries, as the medical writers of the time regularly recommended water-based cures for the treatment of various ailments. No more is this relationship more apparent than with the huge thermo-mineral bath centers in places such as Baiae in the Bay of Naples (Italy) and Allianoi in modern Turkey (located some 20 km northwest of ancient Pergamon). Thermo-mineral resorts such as these were extremely popular healing and holiday destinations, with the town of Baiae in particular gaining a reputation as a debauched playground of the well-to-do. Baiae was a very long-lived resort, in use from at least the early

Baths and Bathing, Roman, Fig. 4 Axonometric restoration of the Imperial Bath-Gymnasium complex at Sardis. (© Fikret Yegül (after Yegül 2010: 164, Fig. 74))

Roman Republican period through to the seventeenth century CE. Allianoi made the news again recently, threatened ironically by the very thing that gave it life – water – with the construction of the Yortanli dam condemning this ancient health retreat to be lost once more to history in late 2010/early 2011.

Houses, Villas, and Palaces

Bathing facilities were a common, but by no means universal, feature of domestic properties throughout the Empire. These ranged in size from small bathrooms with a simple tub through to luxurious miniature versions of public bathing establishments for use by several individuals simultaneously, be they family, friends, or business associates. Some of the best-preserved early examples are, not surprisingly, from the towns of Pompeii and Herculaneum; however, from the later Roman period, several huge and centrally located residences have been found in cities throughout the Empire, including Constantinople and Athens (Fig. 5). These buildings are sometimes referred to as palaces, with bathing facilities on par with their more public brethren.

It is important to stress that not every property had elaborate bathing facilities; this is especially true of the multistory apartment complexes (*insulae*) where the greater urban population lived in Rome and other large cities. For these people the public baths were a vital utility.

Church/Baptistery Baths

The adoption of Christianity as the official religion of the Empire over the course of the fourth century CE did not halt the construction and use of

Baths and Bathing, Roman, Fig. 5 Cut-away perspective of the Palace of the Giants by J. Travlos. (© American School of Classical Studies at Athens: Agora Excavations)

public baths. Indeed, it was not uncommon to build baths in connection with churches and monasteries or to utilize preexisting bathing establishments as baptisteries (see section "Historical Background").

Historical Background

Origins of the Roman Bath

The origins of Roman public bathing may be sought from several sources, although the degree of influence imparted by each source is debated and routinely subject to reassessment when new evidence is uncovered or published. A major influence is undoubtedly to be found in the long-standing public bathing and gymnastic habits of the classical and Hellenistic Greek world, especially from the Greek colonies in South Italy and Sicily (see the entry on "▶ Baths and Bathing, Greek", in this encyclopedia). There is also evidence to suggest that local bathing traditions of rural central Italy may have played their part in the development of Roman-style bathing and architecture, most notably through the use of bathing rooms with graduated temperatures in their farm houses (Varro *Ling*. 9.68; Fagan 2001: 417; Yegül 2010: 45–7). The influence of Etruscan and Punic public bathing habits on Roman bathing habits is currently less well understood.

The development of the hypocaust is a popular topic of debate. Based on the writings of Pliny the Elder (*Natural History* 9.168) and Valerius Maximus (11.1.1), the tradition has been to link the development of the hypocaust to the Campanian oyster farmer and merchant Sergius Orata (flourished c. 90 BCE–80 BCE), but the archaeological evidence (and critical literary analysis) shows that this is incorrect. Examples of fully fledged hypocausts are known already from Central Italy at Fregellae (Latium) in the early second century BCE, from the late second century BCE in Pompeii (Stabian Baths), and from the second and first centuries BCE in Greece (Gortys, Olympia, and Athens) and Sicily (Megara Hyblaea) (DeLaine 1989; McCallum 2010; see the entry on "▶ Baths and Bathing, Greek" in this encyclopedia), while more simple predecessors are known already in the Eastern Mediterranean from the sixth century BCE onwards (DeLaine 1989; Fagan 2001; Yegül 2010, 81–2, 84–6; see the entry on "▶ Baths and Bathing, Greek", in this encyclopedia). Wall heating (tubulation) on the other hand is considered to be of completely Roman/Italian origin (Yegül 2010: 86; although note the recent evidence from Taposiris Magna in Egypt and the hollow walls at Gortys mentioned in DeLaine 1989: 112).

The thermo-mineral resorts at Baiae and Himera in Sicily were in use from at least the early stages of the Republican period. It is therefore possible that aspects of the later public baths, such as the large communal pools, advanced heating systems, and not least the acceptance of public bathing as an enjoyable and socially acceptable event in Rome, may have some roots here (DeLaine 1989: 123; Fagan 2001; Yegül 2010: 49–50).

Whatever the exact origins of the Roman style of bathing, it is clear from the archaeology and their appearance in the literary sources that they were certainly a feature of Republican Roman life from at least the third century BCE onwards and that making a visit to a public bath became a commonplace daily event over the course of the second to first centuries BCE. As mentioned previously, the Roman bathing habit spread with the Empire. Those provinces with pre-existing public bathing cultures incorporated Roman bathing norms to differing degrees (notably in the Hellenized East and Egypt), but the adoption of Roman technologies and habits is seen everywhere to some extent.

Christianity

Over time, as to be expected, there are some changes to the public bathing habit, but the core experience remained fairly stable for an extraordinarily extended period. Even after Christianity was adopted as the official religion of the Empire during the fourth century CE we do not see an instant effect on the popularity of the baths, and there was certainly no universal ban on public bathing or even seriously sustained official opposition from the Church. Indeed, in some instances, the Church owned and operated public baths as a

profitable business, and other times we see baths used for ablutions on religious holidays or attached to churches and monasteries for use as charity baths or for baptisms (Nielsen 1990: 147–8; Yegül 2010: 185, 202–3). Even bishops and monks were known to bathe in the baths and sometimes even with women (Nielsen 1990: 147).

There was some Christian opposition to the excessive wealth displayed at the baths and the phenomenon of mixed bathing (Nielsen 1990: 148 and see below) as well as to some of the more pleasurable and extracurricular aspects of a visit to the bath. We see this expressed clearly in the late sixth century CE by Pope Gregory the Great (540–604): "[Baths are] for the needs of the body. . .not for the titillation of the mind and sensuous pleasure" (Gregorius I Papa *Registrum Epistolarum* I, xiii, 3; Yegül 2010: 204). Additionally, some devotees did pursue the concept of *alousia* (abstinence from washing), but it was nothing like the phenomenon seen in Europe for some two centuries from the mid-sixteenth century CE. More serious was Christian opposition to exercise and nudity and indeed the whole cultural and educational institution of the gymnasium; this did lead to the dwindling of the gymnasium/exercise segment of the baths. The effects of this opposition were especially clear in the East, where the bath-gymnasium complexes had previously been so popular (Yegül 2010: 182, Chapter 11).

The Decline of the Roman Bathing Habit

While the Roman public bathing habit in some sense never ceased completely (it still lives on in altered form in the Turkish bathing habit), by the seventh century CE, and earlier in many places, it had undoubtedly ceased to be the widespread and integral social institution it once was. So what caused this to happen?

The downfall of many of the bathing establishments, especially the larger ones, can be linked to the civic and economic disorder and profound societal changes brought about by various "barbarian" incursions in Rome and throughout the Empire during the so-called Migration Period in the fifth through eighth centuries CE; the fate of the large baths was inextricably linked to the fate of the wider city. In a time of regular infrastructure damage, severe hardship, and depopulation, cities were simply unable to repair and maintain multiple city baths – they were too expensive to keep running, and, critically, they required a functional and plentiful water supply. The aqueducts, which could run for dozens of kilometers outside of the city, were especially prone to sullying or destruction by besieging armies, and priority was needed to be given to drinking water over the baths.

Baths continued to be built and maintained much later in the East than West, perhaps due to a more stable environment during these centuries of upheaval and change, but even these baths were in serious decline by the ninth century CE (Yegül 2010: 200). Undoubtedly, some of the thousands of smaller bathing establishments, with their much more modest water-supply needs, continued operating in some form or another, especially in the early Islamic East, where public bathing has continued through to the modern hammam still used in places like Turkey, Syria, Iran, and Tunisia today. We also know that many thermo-mineral health resorts remained in use over the next 1000 years, most notably Baiae, which, as mentioned previously, continued in use until the seventeenth century. Despite the existence of these remnants of Roman bathing, it is clear that by the seventh century CE, the public baths had ceased to be a cornerstone of daily life.

Key Issues/Current Debates

While the Roman baths have received scholarly treatment at various times previously, interest in baths and the act of bathing in the Roman world has increased dramatically in the past 30 years, most notably through the 1980s and 1990s when there was a surge of literature and new approaches to balneological studies (including, but certainly not limited to, general works by Brödner (1983), Heinz (1983), Pasquinucci (1987), Nielsen (1990), Yegül (1992, 2010), Fagan (1999, 2001), and DeLaine and Johnston (1999); also several important articles by DeLaine that critically assess the state of the discipline, DeLaine (1988, 1992, 1993, 1999a, b); and the comprehensive bibliographies compiled by Manderscheid in 1988 and

2004). This expanding scholarly corpus has incorporated the archaeological, literary, and epigraphic evidence over a vast chronological and geographical scale to provide us with a reasonably solid understanding of many aspects of the practical, physical, social, technological, and cultural aspects of bathing during the Roman period. Several of the current, and in some cases seemingly eternal, debates and key issues have been touched upon already (origins of the Roman style, developments over time, how they were perceived, their role as agents of Romanization, and the reasons behind the eventual decline of the Roman-style bathing habit); now three more are briefly addressed: "Who was bathing?" "How widespread was mixed bathing?" and "Why were the baths so popular?"

Who Was Bathing?

The question of who was bathing in the public baths is complicated in the sense that we are dealing with such disparate evidence over a huge expanse of geography and time. Further exacerbating this state of affairs is that the situation would have varied from bath to bath. Individual bathing establishments varied not only in size but also in degree of accessibility and exclusivity. While the largest baths catered for most, if not all, elements of the population with their immense size and cheap or free bathing (male/female, adult/child, rich/poor, and apparently even slave), the vast majority of baths were smaller facilities, inevitably catering to a more limited clientele based purely on their size alone. It is then perhaps best to envisage, and the sources suggests as much, that most public bathing establishments were similar to the nightclubs, cafes, or pubs of many modern cities. A particular bath attracted a certain clientele based on their facilities, decor, location, cleanliness, entry charge, and reputation (which could change very quickly). The choice of bath was apparently important enough among high society that one could enquire of a stranger which baths they used (Ammianus Marcellinus 28.4.10; Fagan 1999: 20). Furthermore, some bathing facilities explicitly served a specific gender, class, guild, or religious group, and of course those baths operating inside sanctuaries and military camps, or attached to buildings such as gymnasia and the like, would have all been accessed by, and potentially restricted to, certain groups. By gaining an understanding of the various locational contexts of bathhouses, we open a window into the principles of social ordering of the people who utilized these facilities.

How Widespread Was Mixed Bathing?

That both men and women around the Empire utilized the public baths is beyond all doubt, but the extent to which men and women bathed together has been a regular source of debate and disagreement. There can be no doubt that mixed bathing did occur throughout the long history of Roman baths (indeed several emperors and even the Church attempted, unsuccessfully, to legislate against it, with the last decree coming as late as the eighth century CE), but the degree to which it was the norm or how much it varied from place to place over time and facility is uncertain. The available evidence reveals several solutions when it comes to men and women using the baths:

1. Separate establishments for men and women (a phenomenon more common in the earliest and latest Roman baths).
2. A single establishment with separate entrances and duplicated facilities (not necessarily of identical size or quality). Not all facilities were duplicated in some baths, suggesting some shared areas in those instances.
3. A single establishment with different bathing times for men and women. This solution is still seen today in some hammams (Turkish baths).
4. Freely mixed bathing (a regular theme in Martial and Imperial decrees).

Why So Popular?

The vast popularity of the public baths can be explained citing both practical and sociocultural reasons. The core function of public baths was obviously to get clean, and this was an important community service in a time when bathing facilities in many homes were simple or nonexistent. Bathing in water is in itself a physiologically relaxing and pleasurable experience. This experience, coupled with the communal aspects of the baths

(socializing, networking, seeing, and being seen), ensured that bathing was a relaxed, potentially intimate, and important social event. Over time, these characteristics led to bathing becoming a daily habit ingrained in the social flow of Roman society, which in turn caused the facilities, both bathing and secondary, to be expanded and improved. As the secondary facilities and services expanded, people would have even more reason to spend more time in the pleasant environment of the baths (they could eat, drink, exercise, primp, study, and socialize all in the one building). The extreme popularity of the baths led emperors, local officials, and other rich benefactors to construct and maintain ever larger and awe-inspiring edifices, for both the public benefit and to increase their reputation among the populous. By offering heavily subsidized or even free entry, they could further enhance the positive effect for both themselves and the baths. This cycle fed on itself for centuries, and the public baths became arguably the dominant social and cultural institution in the Roman world, to the extent that by the late Roman period, the largest baths in some towns had overtaken several of the social and political functions of the forum.

Future Directions

With the relatively recent surge in bath-related scholarship, our knowledge of Roman baths and bathing has increased markedly. However, there is still plenty of important work to do, especially at the individual, local, and regional levels. Thanks to the central and long-lived role baths played in Roman society (both in the heartland and the provinces), their ubiquitousness within most settlements, and the sturdy nature of their construction, new evidence for baths is regularly being uncovered. Improved excavation and data collection techniques ensure that the baths being excavated today can provide us with much more information than was previously possible. This, coupled with an abundance of previously exposed material that has either never been published or only summarily published, means there is fundamental work to do at the level of individual bathing establishments.

Similarly, while many have examined baths at local and regional levels in the past, there is a great disparity in the quantity and quality of work that has been done. By gaining deeper understandings at the local and regional levels (where there is quite a lot of variation), we will be in a much stronger position to discuss how the baths and Roman bathing culture were integrated and utilized in the disparate corners of the Empire.

At the general level, fundamental questions concerning origins, development, transformation, and decline are still open for further discussion, and there remains more to learn about the functioning of baths in their various contexts, their decoration, secondary facilities, and post-Roman existence, particularly in the West.

In a topic so universal and fundamental to the Roman experience as the baths, the potential and importance of continued study is clear. Future directions for balneological studies are almost as numerous as the baths themselves. Evidence, both old and new and archaeological and literary, needs to be (re)appraised using current analytical methods and theoretical frameworks. Coupled with the magnificent opportunities provided by advances in digital technology and cloud computing, there is tremendous potential for different questions to be asked and new perspectives to be gained in the world of Roman bathing.

One such digital project, to be undertaken by the author, is an online catalog of Greek and Roman baths. Previously, two major general catalogs of Roman baths have been compiled featuring baths from throughout the Empire: Manderscheid (1988/2004), which is in essence a collection of bibliographic references but also works as a catalog, and Nielsen (1990), who cataloged 387 baths. Due to their wide-ranging nature, self-imposed limits, and increasing age, these lists are invariably incomplete, but they nevertheless provide an excellent starting point for future research. Building on these solid foundations, the author is in the very early stages of developing and implementing a multi-relational online database to allow information on baths, Roman and otherwise, from all over the Mediterranean and beyond to be cataloged and available in a freely accessible and easily updatable website. The author will add more information about this online database as work progresses.

Battlefield Archaeology

John Carman
Institute of Archaeology and Antiquity, University of Birmingham, Edgbaston, Birmingham, UK

Introduction

A dedicated archaeological approach to the study of historic battlefields is a recent development, beginning with work at the Little Bighorn, USA battlefield in the 1980s where the methodology of

using metal detectors to locate spent bullets was first applied. Since then, it has spread to the UK and mainland Europe, with some work in other parts of the globe. While the battlefield archaeology community is still relatively small, interest in the field has grown so it now can boast regular conference series and a dedicated journal, as well as more than one course of formal study.

Definition

Battlefield archaeology is a term used in two ways. In one – very specific – sense (and the one used in this entry), it is the application of particular techniques to study the material residues of past battles. As used in this sense, it focuses upon sites where armies came together to engage in a formalized style of fighting which was heavily rule bound and sanctioned. Battlefield archaeology generally therefore excludes sites of conflict between less organized bodies of armed people such as uprisings and revolts, sieges, and smaller and more fluid military actions such as skirmishes.

In a second, looser, sense it covers the archaeological study of all aspects of conflict from the most ancient to the most recent, regardless of period or style, and not limited to sites of violence but extending to military encampments and bases, issues of logistics, prisoner-of-war camps, and the location and reburial of the dead from past wars. The currently preferred term for this wider concern is "conflict archaeology," with "battlefield archaeology" reserved for its more specific sense (Fig. 1).

The archaeology of historic battlefields requires, as well as the usual skills of the archaeologist, a specific set of techniques and technology. While some battlefields will contain built features – trenches, walls, palisades, and other earthworks, buildings, and mass graves – to be surveyed, excavated, and interpreted in accordance with standard archaeological practice, others do not. For these, the primary evidence will come from scatters of material left in the topsoil or plowsoil and detectable by metal detector. The evidence that is available will depend upon the period of the fight, the weapons used, the type of action – whether mainly infantry or mainly cavalry – and postdeposition factors that will determine survivability. As well as soil chemistry, overbuilding, and changes in land use, the effects of collecting and looting will have significant impacts upon the material.

Historical Background

While battles as events have been the focus of historical interest since the discipline of history

Battlefield Archaeology, Fig. 1 Metal detector survey at the Oudenaarde battlefield, Belgium, September 2011

was first invented, a specific interest in the material record of battlefields took longer to develop. Early efforts include those of Edward Fitzgerald from 1842, whose work at Naseby in England includes the recording of field names and other topographical features, drawing the contemporary appearance of the landscape, noting where local people had found artifacts from the battle, and recording where local tradition placed particular events of the battle. Fitzgerald's work went on to include the digging of test pits and finding a mass grave. At about the same time, Richard Brooke was pursuing his interest in the battlefields of the Wars of the Roses, inspired in him by his birth near the site of the battle of Stoke. His *Visits to the Battlefields in England of the Fifteenth Century* comprises largely discussions of the historical sources he drew upon and concerns the events of the fight and the names of the prominent killed and wounded. He does, however, provide useful sketch maps of each site, some of which are of more practical use today than more modern ones.

Subsequent interest has largely remained in the realm of Brooke's primary concern, of identifying the places where battles took place, rather than using them as research objects in their own right. Once identified, the tendency is to assume that the landscape as seen today is similar – if not identical – to that on the day of the battle. As Foard makes clear in his criticism of both the standard form of battlefield "guide" and the English Heritage *Register* (1995) which so closely resembles such guides, most publications on battlefields continue to "place stylised battle formations and key topographical features… almost arbitrarily against a modern map base" (Foard 2001: 88). Frequently, however, students of military history have taken the trouble to visit the sites of the battles they discuss and to relate the topography to contemporary accounts. Nevertheless, the primary focus has always been upon the literary evidence for battle action, rather than what evidence the place itself could provide.

However, a group of unrelated twentieth-century research moved closer to a direct concern with the battlefield itself, and while all have much to teach us in pursuing this field, only the last has led to the recent explosion of interest in battlefield archaeology. The first exercise in battlefield archaeology in the twentieth century took place in the late 1950s and early 1960s, when the then military government of Portugal sought – among other things – to celebrate Portugal's military past by promoting the deeds of its medieval chivalry. Excavations in advance of building a monument and a museum at the site of the battle of Aljubarotta, where Portugal first emerged as an independent state, revealed a mass grave and battlefield features. This exercise in battlefield archaeology has gone largely unnoticed by the battlefield archaeology community. A decade later in England, work at Marston Moor (an English Civil War battle site) and roughly contemporary geological work at Maldon (site of a Viking attack on the East Saxons, CE 991), testify to the importance of topographical research and careful reconstruction of the historic landscape by revealing how accounts based upon the modern appearance can be highly misleading. At Marston Moor, the realization that the sunken road which played such a large part in nineteenth- and twentieth-century accounts of the battle was a feature added in the eighteenth century (and therefore was not present on the day of the battle) altered understanding of contemporary seventeenth-century accounts. At Maldon, confirmation that a significant change in sea level had occurred from the tenth century to the twentieth forced a reassessment of the one contemporary account of the battle; this in turn required the removal from the accepted story of the battle several events which had been added later to allow the modern appearance of the site to fit the ancient account (see Carman and Carman 2006: 7–8).

The combination of careful recording of artifact scatters, topographic research, and the search for remains of the dead at the Little Bighorn site in the USA (Scott et al. 1989) finally brought battlefield archaeology attention, and these techniques have since been applied in the USA at Palo Alto, Texas (Haecker and Mauck 1997), in the UK at Towton (Fiorato et al. 2000), and elsewhere (e.g., see Freeman and Pollard 2001; Pollard and Banks 2006; Scott et al. 2007). As a result of successful battlefield archaeology projects in a number of

countries, the number of specialist battlefield archaeologists in Europe has grown over the years and the field is increasingly recognized as one of significance. The most recent *Fields of Conflict* conference – the leading conference in the field – held in Germany had participants from 14 countries of Europe as well as the USA and Canada.

Key Issues and Current Debates

Practitioners of battlefield archaeology have in general been more concerned with issues of methodology than other aspects of the field. In part, this is because the techniques are still under development and – although there is general agreement on the approach to be taken – questions arise as to specifics. In part, it is because both the underlying purpose of battlefield archaeology and the underlying theory go unquestioned. The purpose is generally taken to be to provide an insight into past military practice, drawing on inspiration from military history. The theoretical approach, whether acknowledged or not, is an overtly processualist one, deriving directly from the search for "patterns" – as evident in the work on the Little Bighorn site. Despite the expressly anthropological concerns of that research, more recent attempts to incorporate anthropological theories of war into the field (e.g., Carman and Carman 2006) have generally been resisted.

The much-cited book *Archaeological Perspectives on the Battle of the Little Bighorn* (Scott et al. 1989) is largely the inspiration for the rise of battlefield archaeology over the past two decades. Taking advantage of the cutting of the grass at the Custer Memorial site, Scott and his colleagues used metal detectors to trace the fall of bullets and the ejection of cartridges across the space of the fight between units of the seventh US Cavalry and Lakota and Cheyenne warriors. Differences in weapons used by one group of participants from those used by others allowed the researchers to identify Native American shot from that of the soldiers, and the distribution especially of cartridge cases across the space identified the movement of individual weapons – and therefore of men and formations – through the space. From this, a model of the sequence of events emerged which confirmed Native American accounts frequently dismissed. Other work on soldier burial sites allowed also the identification of individuals, the opportunity to infer the location of the bodies of missing soldiers, and the chance to develop a picture of the "typical" soldier for the late nineteenth century in North America. In particular, the researchers sought to identify the "patterns" revealed by the distribution of bullets across the space: the "static" pattern of the present distribution of bullets and casings, the "dynamic" pattern of movement through space this represented, and from this the standardized "post-Civil War battlefield pattern" of military behavior that would provide a model for interpreting other sites of the period.

A combination of discussions by Pratt and Sivilich (see papers in Scott et al. 2007) allows an appreciation of the techniques of battlefield archaeology as they have developed since the 1980s. Pratt outlines an effective survey technique by metal detector, whereby two operators survey an area, each using a different machine and at a 90° angle to one another, locating individual finds on a GPS recorder. As he puts it, by using this survey technique, "coverage [of ground] is improved and typically result[s in an] increase of collected artifacts or more thoroughly substantiates the lack of metal remains" (Scott et al. 2007: 8). Sivilich in the same volume provides a useful survey of what can be learned from musket balls deposited on pre- to mid-nineteenth-century battlefield sites, which (because they are used in smooth-bored weapons and are lacking the distinctive features of rifle markings) cannot be associated with individual weapons. These include an idea of the type of weapon for which the ball was made, derived from its diameter and weight. Similarly, it is possible to identify whether it had been fired – from scorching and powder burns on one side and the distinctive "ring" around the center caused by scraping along the inside of the gun barrel – or dropped, by the continued presence of mold seams and sprues from manufacture. A scatter of fired bullets can be assumed to have

been aimed at a target but to have missed it unless deformed and to have traveled beyond it, whereas bullets fired and deformed may have hit the target but with insufficient force to cause harm: A combination of this information may indicate where the soldiers being fired at stood. A scatter of dropped bullets may indicate where firing soldiers stood. A particular development has been experimental work on firearms in order to ascertain what finds of shot on sites of battle may indicate. It is clear that fired bullets discovered by metal detector will mostly have failed to hit a target, but what is not immediately obvious is how far the bullet may have traveled beyond where any target was standing and how it may have been deflected by bouncing. Examples include work on case shot and on eighteenth-century muskets in the USA. Although not – as at Little Bighorn – indicating the movement of weapons and therefore individuals through the battlefield space, this kind of information can inform an understanding of the placement of troops during the action.

A central issue remains the search for sites to investigate. The precise location of battles from earlier historical periods is rarely known from written records, and much effort can be spent in locating them. In recent years, two battles from the Roman period have been securely located entirely by archaeological effort, both in northern Germany: Kalkriese, the site of the destruction of Varus' three legions in CE 9 (Rost 2007; Wilbers-Rost 2007), and a previously unknown action from the third century CE at Harzhorn. In both cases, scatters of material brought archaeologists to the site, and careful analysis of the distribution allowed an understanding of the fight to be constructed. At Kalkriese, excavations brought to light the barrier constructed by the Germans to prevent the escape of Roman troops into the surrounding country, thereby trapping them between attackers and swampy ground.

Elsewhere, a combination of material scatters and close reading of the available textual evidence allowed the identification of the likely site of the eleventh-century CE battle of Fulford in England (Jones 2011). Close reading of topographic descriptions contained in the main contemporary texts allowed the identification of likely locations. Environmental and other survey then established the extent to which each of them might match the description given in those texts. Survey by metal detector then sought to locate the material evidence at each site that a battle of the period had taken place. What was found – rather than scatters of weaponry such as arrowheads, broken swords, and spears – was intensive evidence of metalworking, including artifacts such as anvils and other metalworking tools, the bases of hearths, and incomplete and unfinished metal objects such as arrowheads. In similar vein – but also including an explicit search for evidence of fighting – the much later battle of Bosworth was finally located only in 2009 after extensive topographical research supported by metal detector survey.

The problems of investigating earlier sites are well recognized by battlefield archaeologists. It is therefore no surprise that the bulk of battlefield research focuses on later periods, where the location of actions is more firmly established. Such work covers the periods from the sixteenth to the nineteenth centuries, with clusters around certain periods within that time frame. Here, other questions dominate. In particular, in an effort to establish the value and legitimacy of battlefield research, effort has been spent on proving the techniques of battlefield archaeology to official agencies who are then encouraged to arrange for the preservation of key sites so that they will in turn become available for investigation and study.

However, battlefield archaeology is no more than 15 years old in Europe and is still young as a specialized field. Techniques are increasingly well established, an increasing number of scholars are taking an interest, and broader research questions – such as the development of gunpowder warfare from the fifteenth to seventeenth centuries – are emerging. Although a close-knit community of battlefield archaeologists has been formed, especially through the *Fields of Conflict* conferences from 2001, the largest impact of developments in the field has yet to be recognized, and the recognition by official agencies of the value of this kind of work has also yet to be achieved beyond English-speaking countries.

International Perspectives

Battlefield archaeology was until recently an entirely Anglophone field, limited to American, Irish, and British archaeologists. However, it is now a global field with practitioners from all across Europe and beyond.

In the USA, much work focuses on battles from the nineteenth century. The work at the Little Bighorn site established the basic techniques of battlefield survey by metal detector and established the value of such an approach (Scott et al. 1989). Such work has since expanded to the battles of the American Civil War (Geier and Potter 2001) and to other military actions against Native Americans (see papers in Scott et al. 2007).

In much of Europe, the focus lies upon earlier periods – especially the seventeenth and eighteenth centuries. The last battles in England and Scotland were fought in 1685 and 1746, respectively, and so British battlefield archaeology in particular has focused on these centuries. Foard has worked extensively on the battlefields of Naseby and especially Edgehill, both of the English Civil War of the mid-seventeenth century. Edgehill remains the only early modern battlefield to have been subject to total survey, following extensive historical and topographical research to reconstruct the seventeenth-century landscape. This, together with metal detector survey, established that the traditional accounts of the battle were seriously wrong in the way they positioned troops, affecting any understanding of the course of the action (Foard 2005). Work at Naseby also provided a revised sequence for the battle, including evidence for initial success by Royalist infantry, and their "fighting retreat" after subsequent defeat (http://battlefieldstrust.com/). At Culloden in Scotland, survey in advance of the construction of a new visitor's center soon established that the traditional accounts of the action and its limitation to certain ground only were incorrect (Pollard 2006). Elsewhere in Europe, research on battlefields of these periods has been carried out and is ongoing in Belgium at Oudenaarde, in Germany at Lützen, in the Ukraine at Poltava, in Sweden at Landskrona (Knarrström 2006), and in Spain at Almenar and Talamanca (Rubio 2008).

A limited amount of work has been undertaken beyond North America and Europe, including preliminary surveys of nineteenth-century battlefields in South America (Pollard 2007).

Future Directions

The identification of unknown or disputed sites has led battlefield archaeologists into periods otherwise little examined and where it is uncertain what material residues of conflict may be encountered. These "signatures" (Sutherland and Holst 2005) are well known for battles of the seventeenth to nineteenth centuries where firearms predominate, but for earlier periods are less clear. The work at both Kalkriese (CE 9) and Fulford (1066) suggest that a key indicator of early battle sites may not be deposits of weapons, such as arrowheads, or of human remains, as at Towton (1461), but evidence of prebattle metalworking.

Some historic periods suffer from a lack of explicit focus. The sixteenth century in Europe, although a period that may be considered significant in terms of a shift of warfare style from "shock" to gunpowder and the commencement of Europe's global expansion as a colonizing force, is relatively untouched apart from studies of fortifications or shipping. However, work on sites related to Spanish expeditions into North America in this period provides an interesting alternative approach (see Scott et al. 2007). The late nineteenth century is also low in coverage, except for North American conflict with Native Americans: This may partly be explained by the generally successful exportation of warfare by the major European states to colonial contexts from the close of the Napoleonic Wars to 1914. There are some exceptions to this general rule such as the Crimean War, the Franco-Austrian and Franco-Prussian Wars, and the wars of German and other national unifications from mid-century, although these too remain largely unexamined from an archaeological perspective. Consequently, there is a chronological leap from the eighteenth century to the twentieth century, the

latter forming an entirely separate area of study from that of the historic period (Schofield et al. 2002).

Further developments which are beginning to emerge include the recognition that the archaeology of periods beyond those of the historic may have things to contribute to the study of historic battlefields (Carman 2012). However, the battlefield archaeology of more recent periods remains an issue to be addressed: The standard techniques of battlefield archaeology – landscape regression and metal detector survey – do not necessarily lend themselves well to reinterpretations of the sites of the large and highly technological warfare of the last century, confirming this as a separate field of investigation.

Bauer, Alexander

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Basic Biographical Information

Alexander A. Bauer is an archaeologist whose research foci are the archaeology of the Near East and Eurasia, ancient trade, archaeological method and theory, archaeological ethics, and cultural heritage law and policy. Having studied the prehistory of the eastern Mediterranean as an undergraduate in the Department of Classical and Near Eastern Archaeology at Bryn Mawr College with professors James C. Wright and J.P. Dessel, he earned his Ph.D. in anthropology at the University of Pennsylvania in 2006, where he studied interregional interaction during the pre-Colonial period of the Black Sea region, first under the guidance of Dr. Fredrik T. Hiebert and then Dr. Robert W. Preucel. He is currently an assistant professor of anthropology at Queens College and the Graduate Center of the City University of New York.

Major Accomplishments

Since 2005, Dr. Bauer has served as the editor (in chief) of the *International Journal of Cultural Property*, an interdisciplinary journal on cultural heritage law and policy. He has conducted fieldwork in Greece, Israel, Jordan, the United States, and Turkey, where he is currently associate director of the Sinop Regional Archaeological Project, under the direction of Dr. Owen Doonan. He has served as a senior editor of the second edition of the *Oxford Companion to Archaeology* (Oxford University Press, 2012). His 2001 article with Robert W. Preucel entitled "Archaeological Pragmatics" was among the first archaeological engagements with Peircean semiotics, and since then, he has continued to research and write on its utility for archaeology.

Basic Biographical Information

Timothy Beach is a geographer who uses geoarchaeological techniques, such as archaeological geomorphology and pedology, to illuminate the dynamic interrelationships between ancient humans and their environments. Originally from California, he earned his Ph.D. in Geography from the University of Minnesota in 1989, concentrating on geomorphology, soils, and geology. He has taught at Georgetown University in Washington, DC, since 1993, where he currently holds the Cinco Hermanos Chair in Environment and International Affairs. He is also Professor of Geography and Geoscience in the Science, Technology, and International Affairs program at Georgetown's well-known School of Foreign Service. Previously, he was for 8 years the Director of the Center for the Environment at Georgetown. He has been awarded a John Simon Guggenheim Fellowship and has held a Dumbarton Oaks Fellowship in Pre-Columbian Studies. In 2006, he was elected a Fellow of the American Association for the Advancement of Science.

Beach has worked in the United States, Germany, Syria, and Iceland. He has performed fieldwork at important archaeological sites in Turkey (e.g., Beach and Luzzadder-Beach 2008), but the majority of his research, and that for which he is best known, has been carried out in the ancient Maya lowlands, in Mexico, Guatemala, and Belize. In this region, he has participated in many research projects that have focused on different sites to address varied but interrelated scientific problems using a wide range of field and laboratory techniques. Through interdisciplinary collaborations, he has made major contributions to our understanding of ancient Maya climate, agriculture, agricultural intensification, and the development of anthropogenic soils and landscapes. These studies have allowed him to significantly influence the debates surrounding both the origins and collapse of ancient Maya civilization as well as its economy and adaptation (Fig. 1).

Major Accomplishments

In the state of Yucatán, Mexico, he has worked extensively at the important Classic site of Chunchucmil (e.g., Beach 1998), where he has helped elucidate the paradox of an enormous and populous archaeological site situated in a region with low agricultural potential. At Mayapán, also in Yucatán, he has studied the extensive black earth midden that blankets most of the 4 km^2 ceremonial and residential zone of the site, a mysterious anomaly in the region.

His and his colleagues' extensive work in the Pasión River region around Dos Pilas in the Department of Petén, Guatemala, has helped clarify the complexity of the Classic Maya collapse. In contrast to previous paleoclimatic studies that implicated drought as the primary cause of societal implosion at the end of the Classic period

Beach, Timothy, Fig. 1 Map of the Maya region showing important sites where Timothy Beach has carried out geoarchaeological research

(c. CE 800–900), Beach and his colleagues found little evidence for drying. Nor did they find significant evidence for environmental degradation, such as accelerated soil erosion, during the peak of population in the Late Classic period, another favored environmental explanation of the collapse (e.g., Dunning et al. 1998). Subsequently, Beach's intensive research in northwest Belize has reinforced the inference that the Maya collapse was not triggered by a singular, apocalyptic event, such as a drought, or even by a series of them; instead, it was a complex, long-term, and heterogeneous set of processes without a prime mover (Dunning et al. 2012; Luzzadder-Beach et al. 2012).

His work in northwest Belize in the vicinity of Blue Creek has also helped resolve a sometimes contentious dispute about the nature of Maya agricultural intensification. Previous researchers viewed the ancient Maya wetland fields either as similar to the Aztec raised fields in the Valley of Mexico or as a largely natural phenomenon caused by a combination of sea-level rise and associated landscape aggradation. Beach and his colleagues have shown, however, that their more extensive data sets can be better explained by new models that combine elements of both older models with evidence for additional variations in patterns and methods of field construction (e.g., Beach et al. 2009). This work has also clarified the timing and mechanisms of landscape aggradation in the region, which can now be attributed primarily to gypsum precipitation caused by a rising water table, although other factors contributed to a lesser degree (Luzzadder-Beach and Beach 2009).

Beach and his colleagues' work in the large karst depressions that occupy some 40% of the Maya lowlands, known locally as *bajos*, has contributed evidence that these features played an important ecological role in the development of Maya civilization in the Preclassic period (Dunning et al. 2002). Previously, some scholars had argued that these wetlands were marginal environments of little direct significance to Maya cultural evolution.

Beach's scholarship cannot be understood in isolation, for he has collaborated closely with a

number of geographers and archaeologists. Among these collaborations, the closest and most persistent has been that with his partner, Sheryl Luzzadder-Beach, a Professor of Geography at George Mason University in Virginia who specializes in hydrology and water chemistry. Beach has also worked closely with Nicholas P. Dunning, a geographer with similar interests at the University of Cincinnati. Beach's partnerships with archaeologists such as Stephen Houston, Arthur Demarest, Thomas Guderjan, and the late Bruce Dahlin undoubtedly influenced his research by stimulating interactions with specialists investigating related questions using different approaches.

In summary, Tim Beach has contributed significantly to our understanding of ancient Maya civilization. He has helped to dispel the myth of the "pristine landscape," according to which American Indians had only a minimal impact on their environment. Beach's overarching contribution has been to show how the geosciences can paint a detailed and nuanced portrait of cultural ecological history that does not succumb to an overly simplistic environmental determinism. His work illustrates how such a portrait can be realistic, scientific, and humanistic when colored by a fine appreciation of the complexity of human agency and filled in by sufficiently detailed and diverse data.

Beans: Origins and Development

Paul Gepts
Department of Plant Sciences/MS1, Section of Crop and Ecosystem Sciences, University of California, Davis, CA, USA

Basic Species Information

The genus *Phaseolus* comprises some 70–80 species (Freytag and Debouck 2002), distributed exclusively in the Americas (Delgado-Salinas et al. 2006) but with a clear focal point in Mexico and Central America. This region contains the largest number of species of the genus; it also harbors a very diverse range of environments in which the genus *Phaseolus* radiated following the last major tectonic event, namely, the appearance of the Transverse Volcanic Axis in Mexico. It is in this diverse landscape that five *Phaseolus* species were domesticated (Fig. 1). Of these five species, common bean (*P. vulgaris*) is by far the one with the broadest geographic distribution (Fig. 2) and largest agronomic, nutritional, and economic impact. Other domesticated species are runner bean (*P. coccineus*), tepary bean (*P. acutifolius*), lima bean (*P. lunatus*), and year bean (*P. dumosus*). In addition to the Mesoamerican domestications, two additional domestications took place in the Andes, one each for common bean (southern Andes, between southern Peru and northwestern Argentina) and lima bean (western Ecuador).

The five domesticated *Phaseolus* species have overlapping, yet distinct, geographic distributions, ecological adaptations, life histories, and reproductive systems (Table 1 and Fig. 2). Common bean grows in mesic environments (i.e., at intermediate temperatures [yearly average of

Number of domestications	2	1	1 or 2	1	2
Locations of domestication	West-central Mexico	Guatemala	Mexico	Northwest Mexico	Mesoamerica and Ecuador/N. Peru

24 °C] and rainfalls [around 600 mm/year]) at the transition between dry, deciduous, and pine forests. This species is annual with cycle lengths for most varieties from 80 to 120 days. Its reproductive system is primarily autogamous.

Nevertheless, bursts of outcrossing can take place occasionally, which can significantly affect the distribution of genetic diversity within and among populations (Papa et al. 2005; Zizumbo-Villarreal et al. 2005). Runner bean is the domesticated bean species with adaptation to the coolest (and humid) environments. Its tuberous root system, in addition, provides a way for plants to survive winter frosts as new stems can regrow from the roots. Thus, this species is also perennial, surviving for several years. It is an allogamous species, which relies obligatorily on foraging by carpenter bees and humming birds for seed production (Búrquez and Sarukhán 1980). In contrast with runner bean, tepary bean originated in

warmer, arid environments. It is a short-lived (part of its drought adaptation) annual species, with a highly selfing (even cleistogamous) reproductive system. Lima bean is perhaps the species with the broadest adaptation of all five domesticated species. It is generally grown in warmer, more humid environments. It is a long-lived, annual species with a mixed autogamous-allogamous reproductive system. Finally, as a stabilized hybrid between common and runner beans, the year bean has intermediate characteristics between these two parental species.

Domestication has induced drastic changes in the two most domesticated *Phaseolus* species, common and lima bean. These two species show the full array of traits characteristic of crop domestication (the "domestication syndrome"). In these seed-propagated crops, two domestication traits stand out. Compared to their wild progenitors, domesticated varieties show a reduction or elimination of seed dormancy and dispersal. As a consequence, domesticated common and lima beans have ready germination and limited grain loses from premature pod shattering. In addition, in contrast with wild ancestors, which have exclusively a climbing, viny growth habit with indeterminate branches, these two domesticates' growth habits range from viny to a more compact growth habit with fewer and shorter branches. In some cases, domesticated varieties have a bush growth habit and determinate branches. This trend to smaller plants correlates with a more precocious life cycle, an essential characteristic of most agricultural production systems. Additional changes included gigantism (increase in organ size, especially pods and seeds); development of photoperiod insensitivity, which broadened latitudinal adaptation; acquisition of broad phenotypic diversity for the principal harvested organ pods and especially seeds (e.g., the colorful array of domesticated bean seeds) as a result of selection for novelty; and reduction in toxic compounds, such as the cyanogenic glycosides in lima bean. The inheritance of the domestication syndrome has been investigated in common bean (Koinange et al. 1996). The results show that the inheritance of the domestication syndrome in common bean was relatively simple genetically; few, major genes were responsible for a majority of the phenotypic variation (i.e., domestication traits have a generally high heritability). In addition, these genes are distributed on few chromosomes, and several crucial genes seem to be loosely linked. This genetic architecture would allow a relatively speedy evolution under domestication, provided selection was applied regularly and with sufficient strength (Gepts 2004).

Timing and Tracking Domestication

Molecular analyses in wild and domesticated forms of the various domesticated *Phaseolus* species have provided a picture of "hyperdomestication" in the genus. Not only are there five different domesticated species, but two species – common and lima bean – have been domesticated twice (Fig. 1). Common bean was domesticated in western Mexico and the southern Andes (Kwak et al. 2009; Kwak and Gepts 2009; Chacón et al. 2005). Likewise, lima bean was domesticated in Mexico and Ecuador (Gutiérrez-Salgado et al. 1995; Serrano-Serrano et al. 2012). In both species, these two domestications occurred in distinct geographic regions from already diverged wild progenitors (named the Mesoamerican and Andean gene pools). Runner bean was domesticated once (and possibly twice) in Mexico (Angioi et al. 2009). In contrast, both tepary and year bean were domesticated only once, in northwestern Mexico and Guatemala, respectively (Schinkel and Gepts 1988, 1989; Freytag and Debouck 2002; Blair et al. 2012). Within species, some traits have appeared multiple times, adding to the picture of hyperdomestication. One example in common bean is the multiple origin of the determinacy, which originated independently four times in the Andean gene pool and once in the Andean gene pool, based on DNA sequence data of the gene responsible for the determinacy phenotype (Kwak et al. 2012). This sequence or a related one is also responsible for the presence of

Beans: Origins and Development, Table 2 Oldest archaeobotanical remains of *Phaseolus* spp.

Tehuacán Valley, Mexico	*P. coccineus* (domesticated)	Seed, non-carbonized	410	500	Kaplan and Lynch (1999)

determinacy in Mesoamerican and Andean lima beans and in runner bean.

The overall picture created by these domestication studies is one in which farmers have actively shaped the domesticated diversity of beans at multiple taxonomic levels and times and in different areas of the Americas where the genus *Phaseolus* originated. Rather than relying on a single domesticate such as in maize, farmers have adopted different bean species for cultivation in different environments and have further selected – presumably independently – similar phenotypic variation. This may have been made possible by the relatively young age of the genus *Phaseolus* (4–5 Ma; Delgado-Salinas et al. 2006) such that the domestication potential was maintained in part of the genus, while allowing for the development of differential adaptation among species (Kwak et al. 2012).

Archaeological and linguistic data point to the antiquity of bean cultivation both in Mesoamerica and Andean South America. The first archaeobotanical remains of *Phaseolus* were identified in Peru in the nineteenth century (de Candolle 1882). Since then, additional remains have been obtained in both regions (Table 2 and Fig. 2), the oldest of which suggests a presence of domesticated forms by 8,000 years B.P. (^{14}C age) in Peru but only 2,300 years B.P. (^{14}C age) in Mexico. Glottochronological analyses show that the oldest language for which a term for bean has been identified is a Proto-Mayan language (3,400 B.P.; Brown 2006).

The fact that the oldest age available was obtained from micro-remains rather than macro-remains and the glottochronological data suggests that current dates for bean domestication are most likely underestimates. Furthermore, many of the remains originated in very arid areas, outside the distribution of wild progenitors and putative domestication areas determined by genetic means (e.g., west-central Mexico for one of the two common bean domestications: Kwak et al. 2009). Thus, a more active search for archaeobotanical micro-remains (starch grains, phytoliths) in late pre-agricultural or early agricultural contexts should be pursued.

Beaudry, Mary C.

Dan Hicks
Institute of Archaeology, Pitt Rivers Museum, University of Oxford, Oxford, UK

Basic Biographical Information

Mary Carolyn Beaudry is an anthropological archaeologist who has specialized in historical archaeology, mainly in the eastern United States, and has made broad theoretical and practical contributions to household archaeology, the archaeology of gender and inequality, and archaeological material culture studies.

Beaudry received her first degree in Anthropology from the College of William and Mary (1973) and her M.A. (1975) and Ph.D. (1980) in Anthropology from Brown University. Beaudry was advised at Brown by James Deetz, who made a long-lasting impact on her research: an influence most visible in her doctoral thesis, *"Or What Else You Please to Call It": Folk Semantic Domains in Early Virginia Probate Inventories* – which used probate inventories to study the material culture of Virginian households in the seventeenth and eighteenth centuries.

A period working in the cultural resource management sector during the 1980s led to a series of scholarly publications, most notably the 3-volume *Interdisciplinary Investigations of the Boott Mills, Lowell, Massachusetts*, which was edited by Steve Mrozowski. In this publication, Beaudry pioneered methods of associating excavated assemblages with historical households, reconstructed from documentary sources. In 1996, her account of the "boarding households" of nineteenth-century Lowell, written to Mrozowski and Grace Ziesing, contributed an important empirical case study to the development of the archaeology of gender in the United States. Beaudry's edited volume, *Documentary Archaeology in the New World*, developed her interests in the archaeological use of historical documents further.

Major Accomplishments

Beaudry's research into material culture has developed in both theoretical directions – for example, in her 2001 paper with Anne Yentsch on "American Material Culture in Mind, Thought, and Deed" or in her coedited volume *The Oxford Handbook of Material Culture Studies* (2010, edited with Dan Hicks) – and in more applied directions, for example, with her introduction to *Findings: The Material Culture of Needlework and Sewing* (2006). A central theme in such work has been the idea that archaeological material culture can provide distinctive insights into otherwise undocumented lives.

Her most sustained contributions to archaeology have, however, been a series of influential reflections on method and theory in historical archaeology – from her 1996 account of "reinventing historical archaeology" to her coedited *Cambridge Companion to Historical Archaeology* (2006, edited with Dan Hicks).

Beaudry has been an active member of the Society for Historical Archaeology (serving as President in 1989), as well as the Council for Northeast Historical Archaeology, and has been a leading figure in the development of international collaborations and exchanges in historical archaeology, especially between the UK and the USA. While Beaudry's fieldwork has led her as far afield as the Outer Hebrides and Montserrat, it is her sustained contributions to the archaeology of early American life in the eastern United States and to the archaeology of gender and households that has dominated her publication record.

Beazley, Sir John Davidson

Angela Ziskowski
Coe College, Cedar Rapids, IA, USA

Basic Biographical Information

Sir John Davidson Beazley (1885–1970) was a founding figure in the modern study of Greek ceramics. Building on (then innovative) nineteenth-century modes of stylistic analysis, he refined a system of attribution and identification, for Attic pottery with black- and red-figure decoration from the sixth to fourth centuries BCE. He was born in Glasgow, Scotland, to Mark John Murray Beazley and Mary Catherine Davidson. He attended King Edward VI School in Southampton and Christ's Hospital before enrolling in Balliol College, Oxford University. There he excelled and was tutored by the well-known classicists Cyril Bailey and A.W. Pickard-Cambridge. In 1908 he was elected as student and tutor at Christ Church, a position he held until 1925, when he became the Lincoln Professor of Classical Archaeology at Oxford, a position he would hold for the next 30 years. He was knighted in 1949. He met Marie Bloomfield in 1913 and married her on August 13, 1919. They lived and traveled together for forty-eight years, until her death in 1967. Beazley died on May 6, 1970 in Oxford. He and his wife had no children (Ashmole 1970).

Major Accomplishments

Beazley's contribution to the field of Greek archaeology is immense, demonstrated by the publication of over 250 articles and monographs on Greek vase painting and other topics of Classical antiquity (Ashmolean Museum 1967: 177–188). He systematically identified and attributed "hands" of specific vase painters, who were otherwise unknown, by examining the inherent style expressed in their painting. His methodology was based heavily on Giovanni Morelli and Bernard Berenson, who used a similar method to study Renaissance painting (Kurtz 1985: 236). Adolf Fürtwangler, Paul Hartwig, and Friedrich Hauser also influenced his work, although Beazley differentiated himself from these scholars by his emphasis on vase painters of all qualities, not just the masters, and stylistic analysis. Beazley's technique involved the analysis of details such as ears, eyes, drapery of fabric, and decorative details like borders, with the belief that such features were formulaically repeated by an artist (Ashmole 1970: 453–4). In this way, he identified both individual artists and workshops of painters working under one master. His method allowed for the refinement of relative chronology in pottery playing a major role in the dating of archaeological contexts, and his method remains the foundation on which approaches to iconographic and iconological studies in Classical art are based. Scholars such as Martin Robertson and Richard Neer, among others, have since addressed problematic aspects of Beazley's methodology

and attributions (Robertson 1976; Neer 1997). Beazley's most substantial publications were volumes on both red- and black-figure Athenian vase painters from the Archaic and Classical periods. These were *Attic Red-Figure Vase-Painters* (1942) and *Attic Black-Figure Vase-Painters* (1956). In addition, he produced monographs on vases in a large number of collections around the world and wrote a number of works on the Berlin Painter, whom he considered to be his favorite (Ashmole 1970: 454). The "Beazley Archive," built from his collection of photographs, drawings, and notes, is housed at the Ashmolean Museum but also exists as a major online database (http://www.beazley.ox.ac.uk/index.htm). It is now one of the quintessential sources for the study of Greek vases (Beazley Archive n.d.). Students of Beazley, who studied under him at Oxford or trained closely in his methodologies, include Humfry Payne, T. J. Dunbabin, Llewelyn Brown, Dietrich von Bothmer, A.D. Trendall, and Martin Robertson (Ashmole 1970: 451–2).

Beck, Wendy E.

John Appleton
Heritage Futures Research Centre, University of New England, Armidale, NSW, Australia

Basic Biographical Information

Wendy Elizabeth Beck is an Australian archaeologist. She grew up in Melbourne, attended Laburnum Primary School, and graduated from Methodist Ladies College, Kew, in 1975. She completed a B.Sc. at the University of Melbourne during 1976–1978 with a double major in microbiology and biochemistry. After attending a Summer School held by the Victorian Archaeological Survey in 1978–1979, she was converted to archaeology and undertook postgraduate study in prehistory at LaTrobe University (1979–1985). While there she took part in several large research excavations (see Fig. 1). In 1981 she was awarded a Visiting Fellowship from the Australian Institute of Aboriginal Studies which funded her research into Aboriginal toxic food plant processing. Her Ph.D. was awarded in

Beck, Wendy E., Fig. 1 Wendy Beck excavating at Moonlight Head, Victoria, in 1980 (Photo: D. Frankel)

1986 and her principal thesis supervisors were Drs. David Frankel and Neville White, together with AIATSIS mentor Dr. Betty Meehan. Her Ph.D. *Technology, Toxicity and Subsistence: A Study of Australian Aboriginal Plant Food Processing* was the first Victorian doctorate awarded in Australian archaeology and included fieldwork in Arnhem Land in addition to laboratory research. In 1985 she worked as a postdoctoral Fellow (Australian National University) on a bush food dietary project sponsored by the Office of the Supervising Scientist in the Alligator Rivers Region of the Northern Territory. In 1986 she was appointed Lecturer to the Department of Archaeology and Palaeoanthropology, University of New England, NSW, where she is currently employed as Associate Professor.

Beck, Wendy E., Fig. 2 Wendy Beck at Barley Fields Lagoon, New South Wales, in October 2012 (Photo: J. Appleton)

Major Accomplishments

Her most significant contributions to archaeology fall into several fields:

1. Plants and Gendered Archaeology (1981–Present)

Her Ph.D. research concerned Aboriginal plant knowledge and included analysis of a range of different sources: archaeology, ethnographic fieldwork in northern Australia, and documentary resources, as well as laboratory work in chemistry and genetics. She was also interested in the survival and recovery of macroscopic and microscopic plant remains. She coedited the first volume which comprehensively reviewed practical methods as well as research case studies of archaeological plants in Sahul (Beck et al. 1989). Another related issue is gendered archaeology, and she also researches links between plants and women in prehistory as well as women as archaeologists and researchers (Balme & Beck 1995).

2. Place Studies in Archaeology (1989–Present)

Major research interests are how archaeology helps to understand how and why people used spaces and the concept of place as an organizing principle. In her research, there are a number of levels from World Heritage areas, through regions, down to the individual site. Her research in Indigenous community archaeology has also included a number of scales, ranging from the spatial analysis of a single rockshelter (Balme & Beck 2002) to spatial patterns at Gumbaingirr nation level (Beck & Somerville 2002) to upland wetland landscapes (Beck 2006a) (see Fig. 2) and World Heritage places (Beck 2006b). This research has been funded by five Australian Research Council grants. The *Yarrawarra Place Book* series was published jointly by UNE and Yarrawarra Aboriginal Corporation and represented a major research outcome for the 1997 ARC Industry Collaborative Grant project "Ecotourism on the Mid-North Coast of NSW." It presents original research results in archaeology, oral history, and history but presented in an accessible interpretative form. The books and accompanying teacher's kit were shortlisted for a publishing award (The Australian Educational Publishing Awards) and awarded the 2001 ATSIC Many Rivers NAIDOC Community Achievement Award. The first book of the series

(*Arrawarra: Meeting Place*) was also used to develop a school teaching kit with the Australian Marine Parks Authority in 2006. Professor Rosemary Joyce wrote:

> Some of the most engaging contemporary archaeological writing, works that exploit the possibilities of narrative and dialogue to the fullest. . .a series of five interpretative booklets published by the University of New England and the Yarrawarra Aboriginal Corporation. . . .Embedded in a narrative of place, the archaeological reports work both as alternative forms of knowing the place, and as clearly positioned voices with a unique, and consequently valuable, perspective (Joyce 2002: 128).

3. Learning and Teaching in Higher Education (2004–Present)

She has contributed to developing and applying standards in archaeology study, stressing the range of transferable and subject-specific skills which can be gained, as well as how general Humanities degrees can assist students to become employable. In 2009 she was awarded an ongoing Teaching Fellowship by the Australian Learning and Teaching Council for "Improving Graduate Employability by Implementing Subject Benchmarks" which has funded some of her research on standards (Beck & Clarke 2008; Sinclair & Beck in press).

4. Service to the Archaeology Profession (1980–Present)

While in Melbourne as a postgraduate, she was a member and Secretary of the Anthropological and Archaeological Society of Victoria, and after moving to UNE, she became President of the Australian Archaeological Association in 1989–1990. She was founding Chair of the Australian National Committee on Archaeology Learning and Teaching (an AAA subcommittee) in 2005 and continues in an active role. She has been a member of many UNE committees, including Academic Board, Promotions, Ph.D., and Teaching and Learning.

She is a successful earner of competitive research grants and has been awarded over 20 external research grants, worth over $2 million dollars (AUD). Wendy Beck has also been an Australian Research Council (ARC) Assessor for archaeology grant applications from 2001 until the present, and she has reviewed at least 200 ARC applications. She has also completed two large reports for the NSW National Parks and Wildlife Service, *A Cultural Heritage Assessment of Mt. Yarrowyck* (2003 with Somerville, Duley & Kippen) and *Aboriginal Cultural Heritage Offsets in Mining Areas* (2011 with Bartel).

She also has a successful record in fostering the research of others. At UNE she runs successful one-day research writing "retreats" for a wide variety of groups, including both postgraduates as well as Professors (Beck et al. 2008). She has supervised a steady throughput of graduated Higher Degree Research students (D. Donlon, P. Gaynor, R. Cliff, A. Gorman, H. Burke, R. James, D. Vale, S. Martin, R. Fife, C. Clarke) together with B.A. (hons) and dissertation students, most of whom have continued with archaeological careers.

Bednarik, Robert G.

Kirstie Morey
Classics, Archaeology, University of Adelaide, Adelaide, SA, Australia

Basic Biographical Information

Robert Bednarik (Figs. 1 and 2) was born in Vienna but since the 1970s has become a highly regarded Australian-based scholar achieving recognition in the field of prehistoric rock art with a host of publications and projects to his name. His foremost interest lies with the minds of ancient people and how they became human or "civilized;" the origins of the human ability, intellect, and imagination; and in a selection of fields that provide complementary information. This embraces the early stages of art and language and technological growth providing a gauge of early human faculties and capabilities, for example, seafaring, paleo-art of the Ice Age, stone tools, and the use of beads. This talented scholar retains a wry sense of humor despite his immense success and contributions to the field of archaeology, in particular rock art.

Major Accomplishments

Robert Bednarik has held a number of high-profile positions throughout his career. These include being a cofounder of the International Federation of Rock Art Organizations (IFRAO) in 1988; secretary of the Australian Rock Art Research Association (AURA), which he founded in 1983, and editor of its journal, *Rock Art Research*, and monograph series; a national coordinator of the International Comite pour l'art Rupestre (CAR), for the International Council on Monuments and Sites (ICOMOS); and being a member of the International Union of Prehistoric and Protohistoric Sciences (IUSPP) Commission on Rock Art.

Bednarik is a passionate champion of Aboriginal rights, energetically campaigning for Aboriginal control of sites of indigenous heritage, and is frequently engaged in endeavoring to thwart the destruction of rock art worldwide. He has also conducted comprehensive ethnographic research among Aborigines.

Bednarik has cultivated novel techniques for assessing weathering of silica minerals and for studying cave climate; has also created an apparatus to measure the porosity of rock; directed the first comprehensive survey of wall markings in caves; is the pioneer in the investigation of Pleistocene seafaring; and established taphonomic logic in 1993 and metamorphology in 1995. He was one of the earliest individuals in the world to date rock art directly with radiometric methods (reprecipitated carbonates in Malangine Cave, Australia); developed the first non-interfering rock art dating method (microerosion method, initially applied at Lake Onega, Russia); and was

Bednarik, Robert G., Fig. 1 Robert Bednarik at the entrance shaft of the cave art site near Mount Gambier

Bednarik, Robert G., Fig. 2 Senior Rock Art Custodian Monty Hale at huge eastern Pilbara petroglyph site, with IFRAO President R. G. Bednarik

an advocate for advanced statistics in Australian archaeology (Brainerd-Robinson method).

Many of the key scientific discoveries in several countries, including the oldest known rock art in the world, first Paleolithic art of China, first petroglyphs in central India, principal petroglyph concentration in the world (1967–1970, Dampier Archipelago, Western Australia), and a great deal of the cave art of Australia, are a credit to the remarkable work ethic of Bednarik.

Specialized Projects

Robert Bednarik's specialized projects include research into portable Paleolithic art of Eurasia and the beginnings of art and symbolism; early fieldwork at major Pilbara rock art concentrations in Western Australia, undertaken between 1967 and 1970; Pleistocene seafaring and maritime replication studies; and numerous geomorphological and sedimentary/pedological projects.

Robert Bednarik has published over 400 refereed scientific periodicals, in 32 languages, principally in cognitive epistemology and paleo-art studies, also general and replicative archaeology, soil science, speleology, deontology, semiotics, and geomorphology. His overall publication record is over 1200 print publications. He has appeared in several film documentaries and given an excess of 200 interviews with print and electronic media, in many parts of the world.

Robert Bednarik has conducted intensive fieldwork in across the world, especially in central, northern, eastern, western, and southern Europe. He has also undertaken fieldwork in Siberia, India, China, Canada, the USA, Mexico, the Caribbean, various South American countries, southern Africa, Morocco, and in all regions of Australia.

Behavioral Archaeology

William H. Walker[1] and Michael Brian Schiffer[2]
[1]Department of Anthropology, New Mexico State University, Las Cruces, NM, USA
[2]School of Anthropology, University of Arizona, Tucson, AZ, USA

Introduction

Behavioral archaeology is a social science with a unique approach to the study of human behavior. Inspired by the New Archaeology early in the 1970s, J. Jefferson Reid, William L. Rathje, and Michael B. Schiffer ambitiously redefined archaeology as a discipline that focused on the role objects play in all human activities past and present. By giving material objects an active role in behavior, they could extend the rigor of archaeological analyses of artifacts into other social science arenas, giving archaeology a more central role in the production of method and theory. Not surprisingly, behavioral archaeologists developed new models of inference for handling archaeological evidence and material culture. This has led to detailed studies of how technologies are developed and change as well as the extension of behaviorally oriented studies on subjects such as ritual and communication that have typically not been arenas for object-focused studies of behavior. Indeed, behavioral research anticipated the renewed interest in material culture studies described in the recent materiality literature (Hicks and Beaudry 2010).

Definition

Behavioral archaeology is a social science whose subject matter is the interaction between people and other objects (e.g., people, portable artifacts, architecture, places) in all times and places. At the core of behavioral archaeology is the recognition that material objects are not a separate realm acted upon by people but instead are an attribute of human action. In behavioral archaeology, human behavior is defined as interaction between people and things. The material matrix that envelopes people during their entire lives is the proper subject matter of those seeking to understand organization and change in human activities. Thus, behavioral archaeology, while a necessary component of any traditional archaeological research project, reaches beyond that role to understand the material matrix that is the human world of action.

Historical Background

The roots of this material culture-centered approach to behavior lie in reactions to functionalist (1940s and 1950s) and neoclassical evolutionary social theory (1960s and 1970s). In the 1940s and 1950s, functionalist archaeologists broke with visions of cultures as a historically contingent clustering of culture traits (e.g., pottery types, projectile point types, house forms) created by the migrations, innovations, or borrowing of their participants. By theorizing culture as a set of integrated institutions (kinship, religion, politics, economy), artifacts became indirect traces of human activities comprising these institutions. For example, treating artifacts and architecture as the indirect traces of activity led to settlement pattern studies in the 1950s and stimulated the rise of archaeological survey methods and further

inferences about political organization, technology, and human-environment relationships (see Willey and Sabloff 1980). The subsequent 1960s was a revolutionary time in archaeology that inspired many young graduate students to push archaeological boundaries.

New Archaeologists during the 1960s promoted a theoretically driven archaeology, arguing that new questions required new models of culture and its attributes. They redefined cultures as ecologically adapting systems that integrated people, objects, and energy. Employing a neo-evolutionary framework (White 1949), they analytically refashioned functional institutions into adaptive technological, social, and ideological subsystems (Binford 1962). They assumed that technology was at the heart of basic survival, and so these subsystems could be placed in a causal hierarchy with subsistence technologies as the sources of change whose effects rippled up through the social organizational and belief subsystems. New Archaeologists called the generalizations they used to describe causal relationships in these subsystems material correlates or correlates (e.g., Hill 1970). Ethnoarchaeology, which began in the functionalist era, was expanded by the New Archaeology and became a prominent means for developing correlates for building models of past systems and subsystems. It was in this context of change that behavioral archaeology was created.

Two doctoral students working as teaching assistants (J. Jefferson Reid and Michael B. Schiffer) for William L. Rathje at the University of Arizona in the early 1970s argued that archaeology could be its own social science that focused not simply on past peoples or artifacts but instead on the interaction among them in all times and places (Reid et al. 1975). Behavior defined relationally as an interaction with material objects was the analytical lynchpin around which the burgeoning studies of prehistoric, historic, and contemporary societies revolved. They therefore defined behavioral archaeology as "the study of material objects regardless of time and space in order to describe and explain human behavior" (Reid et al. 1975: 210). Their goal was twofold: (1) to systematize what they believed New Archaeology could become and (2) simultaneously address some of its weaknesses.

By the early 1970s, it had become apparent that the systems approach as applied in archaeology tended to obscure or simply ignore lower-scale behavioral variability critical for explaining the structure of archaeological deposits and, arguably, addressing the evolutionary questions that the New Archaeologists posed. Initially, behavioral archaeologists viewed their efforts as consistent with the goals of the New Archaeology.

Trained as a Mayanist, Rathje recognized the symmetry between the study of ancient Maya cities and the study of garbage in contemporary cities and founded the Le Projet du Garbage, applying archaeology to the present (see Rathje and Murphy 1992). Reid and Schiffer developed behavioral archaeology method and theory in their dissertations and subsequent research. Reid (1985, 1995) has largely focused on prehistoric archaeology, while Schiffer has tended to pursue a broader method and theory agenda (see LaMotta and Schiffer 2001). In early work, Schiffer developed a behaviorally based model of inference and applied it in studies of the formation processes of archaeological deposits (Schiffer 1976, 1987). Subsequently he turned his attention to experimental and historical studies of technology (e.g., Schiffer and Skibo 1987; Schiffer et al. 1994a), communication (Schiffer and Miller 1999), and the history of science (e.g., Schiffer 2008). Recent students have expanded the reach of behavioral archaeology to include ritual and religion (Walker 1995, 1998, 2002; Hollenback 2010a), landscapes (Zedeño 1997; Hollenback 2010b), and social power (Walker and Schiffer 2006).

Key Issues/Current Debates

Three broad contributions of behavioral archaeology have shaped debates in the discipline: the synthetic model of inference, a behaviorally based approach to technology studies, and extensions of a behavioral approach to what have traditionally been considered nonbehavioral realms including ritual and religion, communication, and political power.

The Synthetic Model of Inference

Beginning with the New Archaeology's interest in material correlates, behavioralists' initial contributions revolved around systematically laying out a behavioral approach to the material matrix of human activity. They described forms of artifact variability, categories for organizing that variability, and a synthetic model of inference for drawing that variability together in explanations of human behavior. Eventually these studies were pulled together in Schiffer's (1987) *Formation Processes of the Archaeological Record*.

Behavioralists argued that new archaeologists had heavily theorized ongoing cultural systems but that the same could not be said for the proximate activities making up those systems nor for the human and natural actions that instrumentally contributed to the formation of the archaeological record. Initial papers laid out the important distinction between patterning in ongoing cultural systems or "systemic contexts" and patterns in the archaeological record, "archaeological contexts." Behavioralists argued that to link these patterns, we needed to identify the causally connected sequences of behaviors that eventually transformed these patterns from cultural contexts into archaeological contexts (Schiffer 1976; Sullivan III 1978). They described these sequences as "behavioral chains" illustrated by flow models. They also used the more anthropocentric term "life histories" in order to emphasize that human behaviors and lives are inseparable from object histories in the material matrix. To measure patterning in these contexts and sequences of behaviors, they defined four dimensions of archaeological variability: formal, spatial, quantitative, and relational (Rathje and Schiffer 1982; Schiffer 1987). The formal category includes any physical measure that can be taken on an object (weight, specific gravity, completeness, length, width, color, etc.); the other dimensions have more constraints. In any given activity, one or more objects are associated with each other (relational), their frequencies (relative and absolute) can be counted, and their location(s) in space measured. The term correlate, adapted from the new archaeology, became the regularities in interactions between people and objects recognizable in these life histories, measured in relation to the four dimensions of variability.

This research revealed that patterns of cultural deposition could be modeled quantitatively for a community by employing variables such as the number of an object type in use, the length of its use life, duration of use period, and rates of reuse (Schiffer 1976). The implications of these and other variables dramatically changed how archaeologists perceived the opportunities afforded by different sites and archaeological contexts. Any archaeological interpretation requires a series of inferences and can be conceptualized as a series of hypothetical people and object life histories. A behavioral consideration of those hypothetical histories can only lead to better, more-informed interpretations. Even seemingly pedestrian inferences about the dates of an assemblage are deeply enmeshed in formation process questions. How do the relative frequencies of pottery in a site reflect known or hypothesized cultural phases, given the variability in ceramic life histories, as denoted by the variables listed above? Similarly, how does the life history of a piece of organic material with a specific radiocarbon date shed light on the dates of materials associated with it in an archaeological context (Dean 1978)?

The synthetic model of inference drew together various sources of actualistic knowledge, including ethnography, ethnoarchaeology, history, and experiments, to create correlates that could be used in inferences about unknown relationships between past peoples and objects. Such a model necessarily assumes continuities between past and present relationships: (1) the sequential nature of behaviors forming objects' histories, (2) the causal contribution objects make to behaviors that propel the forward motion of activities in life histories, and (3) four kinds of measurement that make possible the empirical study of object performances and life histories. To call attention to the generalizations concerning artifact disposal activities and subsequent archaeological patterning, Schiffer coined the terms c- and n-transforms, which denote the effects that natural and human or cultural processes have on the formation of archaeological deposits. The articulation of this

model and its parts led to a break between new archaeologists and behavioralists.

The Pompeii Premise

The initial discussion of behavioral chains, systemic and archaeological contexts, and the lawlike relationships between people and artifacts, although offered as contributions to the cause of new archaeology, was quickly recognized as different and even threatening by Binford and other new archaeologists because it demonstrated that a realm of messy behavioral variability had not been accounted for in their broad theoretical perspectives. For some new archaeologists, the behavioral perspective became a subject for puerile satire (Flannery 1982), but for others, it represented a theoretical heresy requiring extirpation (Binford 1981). Binford (1964) had claimed that the archaeological record was like a fossil, preserving the skeleton of past cultural subsystems. Behavioralists, however, knew like any taphonomist that the organization of peoples' relationships with objects changed from their living context (systemic context) to the archaeological context and that understanding how that transformation occurred was central to any archaeological inference. Behavioralists therefore criticized metaphorical references to the archaeological record as a fossilized cultural system, labeling them as the Pompeii premise (e.g., Schiffer 1985).

Binford (1981) took up the challenge and a debate ensued over whether there was a Pompeii premise in archaeology. As it was framed by Schiffer and Binford, the issue was whether the archaeological record accurately reflected the past and its implications for archaeological research. Binford argued that it did, while Schiffer (1987) argued that patterning in the archaeological record was a distortion of past cultural systems. Binford uncritically suggested that because Schiffer highlighted the differences in archaeological and systemic contexts and advocated bridging them through the reconstruction of past object life histories, he would only be satisfied to work with Pompeii-like assemblages where the transformations were purportedly trivial. Schiffer argued that to study the proximate causes of variability in archaeological deposits, one had to consider the archaeological record as transformed in order to take advantage of the information offered by any particular archaeological context. In hindsight, this debate concerned two different visions for material culture study and the role of archaeological research in that study.

For Binford, the archaeological record was analytically conceptualized as the product of the interacting subsystems and therefore necessarily if only vaguely encompassed all the variability in life histories of objects, including their disposal, as attributes of the system. Therefore, the system could not be a transformation of itself. For Schiffer and others, the archaeological record was a creation of specific natural and human interactions that changed through the course of peoples' and objects' lives. As such, the debate exposed the differing scales of analysis that were central to the visions behavioralists and New Archaeologists had for archaeology. New Archaeologists had a priori a causal theory of evolutionary change they sought to implement, while behavioralists had an understanding of the material matrix of human behavior they sought to document and explore. Although it was never explicitly stated, this debate seems to have freed behavioralists to pursue their vision without further attempting to justify it within a unified archaeology. They realized that to pursue studies of the material matrix, they would need to shape their own questions, methods, and data independently of the strictures of social evolutionary theory.

Schiffer and others turned their attention to exploring behavioral approaches to technology and expanding the role of behavioral research to topics such as communication and ritual where the material matrix of behavior had been undertheorized.

Technology

Given the expanded understanding of behavior as interaction with objects, it runs awfully close to general understandings of technology. Technologies being central to understanding the material matrix of behavior, behavioralists have focused on how they perform in particular contexts and how they change over time. They elaborated the

concept of performance characteristics for studying activity-based interactions, especially during use (Skibo and Schiffer 2008), and have employed the processes of invention, development, manufacture, and adoption in framing questions about technological change (Schiffer 2011).

Performance Characteristics

Inspired by the work of Braun (1983), behavioralists recognized that to study the behaviors associated with technologies – indeed all interactions with objects – they needed to develop an analytical concept that could capture the causal influences that material objects contribute to interactions with people. Archaeologists had long known that the material properties of objects such as temper in pottery or the toughness of chipped stone tools affected how people used them. Yet analysis of the performance of an object in a specific interaction requires more than a listing of its formal properties. A performance characteristic is a capability, competence, or skill that can be exercised in an activity-specific interaction. Formal properties, influenced by an object's chemical and physical properties, affect performance characteristics. In traditional pottery, for example, temper, surface treatments, and wall thickness affect how rapidly a vessel can heat its contents – a performance characteristic known as heating effectiveness. Heating effectiveness might be favored in cooking pots but not typically in serving vessels. A performance characteristic is a relational construct, not an essential property of an object. Thus, a vessel's closeness to the fire influences its heating effectiveness in a specific cooking activity.

Braun's (1983) interpretation of performance characteristics was focused narrowly on the interactions that an object required in order to perform its utilitarian functions. To accommodate other kinds of interactions, behavioralists have expanded the concept of performance characteristics to include any sort of interaction between objects and other objects, between people and objects, and so forth (Schiffer and Miller 1999; Skibo and Schiffer 2008; Schiffer 2011). And so behavioral archaeologists speak of sensory performance characteristics as relating to basic human senses (sight, sound, touch, taste, smell); performance characteristics also pertain to human competences in, for example, social and economic interactions; thus, an object's replacement cost is a performance characteristic that affects interactions in an acquisition activity. Communication of group identities – indeed any social information – as well as communication with supernatural entities may also be framed in terms of particular performance characteristics. In the hands of behavioral archaeologists, performance characteristics have become a versatile construct essential for studying object interactions of any kind in activities.

Study of Technological Change

In approaching the study of technological change, one of archaeology's oldest preoccupations, behavioralists recognize that generalizations – theories, models, etc. – ought to be process specific, focused either on invention, development, manufacture, or adoption (Schiffer 2011). Thus, in dealing with invention processes, behavioralists have fashioned the cascade and cultural imperative models. The cascade model specifies that during the course of developing a complex technological system (anything from a bow and arrow to a nuclear submarine) performance problems arise. To solve a performance problem requires a burst of inventive activities, which may lead to a solution; further problems are usually encountered, which generate other invention cascades. The cultural imperative model states that the vision of an imagined technology, as defined by anticipated performance characteristics, is held by a constituency, a group of people who believe that its creation is inevitable. Thus, whenever apparently appropriate parts or components become available, a flurry of inventive activities takes place as people strive to materially realize the cultural imperative. It would appear that the cultural imperative model is applicable mainly to industrial societies. Behavioral archaeologists also made contributions to the study of adoption processes by creating the performance matrix – a heuristic for comparing the performance characteristics of two or more technologies among which consumers choose (Schiffer 2010,

2011). A well-constructed performance matrix, which includes all potentially relevant performance characteristics, usually displays patterns, such as one technology that excels in use-related performance characteristics, while another excels in manufacture-related ones. These patterns furnish grist for the archaeologist's explanatory mill. First employed in a study of ceramic change in the eastern United States (Schiffer and Skibo 1987), the performance matrix has been elaborated and employed in diverse studies of technological change (Skibo and Schiffer 2008; Schiffer 2010, 2011).

Performance and the Expansion of Behavioral Studies

Simultaneously with the development of behavioral approaches to archaeological inference and the study of technology, in the 1980s archaeology witnessed the advent of postprocessual archaeology. This new school of thought dramatically changed the landscape of archaeological method and theory. In his postprocessual manifestos, Hodder (e.g., 1985) argued among other ideas that that the "materialist" scientific approaches favored by processualists ignored the roles of peoples' beliefs in shaping their actions, relegating beliefs to the least causal realm of ideology, which left no room for individuals to shape the organization of cultures. Initially this postprocessualism seemed an anathema to behavioral archaeologists who saw themselves as scientists. Many wondered whether the discussion of beliefs and mind would shift attention away from concrete behavioral variability and toward immaterial conceptual variability. However, as debates evolved inside and outside of behavioral archaeology, it became clear that the issue of scale exposed in the Pompeii premise debate was one shared with postprocessualism, as particular behaviors could, independently of the scale of system organization, contribute directly to the formation of archaeological deposits. Further, it was also clear that human behavioral variability extended to any activity involving objects; therefore, activities pertaining to ritual and religion, communication, and technological organization that did not pragmatically relate to subsistence were still interesting and important arenas for behavioral research. Consequently, the postprocessual critiques actually opened up opportunities for behavioralists to show how their approach could be fruitfully applied to these important topics without necessarily accepting the assumptions of postprocessualists concerning the role of science or the centrality of "meaning" as an analytic construct for studying human behavior.

In the 1990s, behavioralists plunged directly into these contested realms. Walker et al. (1995) called this "expanding behavioral archaeology" and referred to themselves as new behavioral archaeologists. They stressed the importance of a relational understanding of behavior and its relevance to a broad range of research topics including ritual site formation processes, political power, and technological change. Given that interactions with material objects take place in ritual and political realms, which also affect archaeological deposits, it made perfect sense to explore how such realms were materially constituted – regardless of one's ultimate stance on evolutionary causal hierarchies. Similarly, given that behavioralists were committed to studying behavior rather than the archaeological record per se, Schiffer could undertake, from a behavioral perspective, case studies of technological change using the history of radios and electric cars (Schiffer 1991; Schiffer et al. 1994b).

Ritual Studies

Walker (1995, 1998, 2002) and others (e.g., Montgomery 1993; Zedeño 2008) have sought to extend the study of behavioral archaeology to include ritual and religion. The lessons learned so far are that – like all behaviors – ritual behaviors contribute to the forward motion of object life histories and that those histories can be identified in the archaeological record because they affect the four dimensions of artifact variability. Like all activity-based interactions, performance characteristics come into play, but they are complicated and cannot be corralled by assumptions about the pragmatic uses of the objects.

A legacy of the New Archaeology's hierarchy of material causality had been a conflation of

those activities deemed materially less causal (i.e., ritual practices) and the material evidence of those activities. It was a traditional assumption, well into the 1990s, that ritual activities left little material evidence. Yet this makes no sense in terms of the material matrix created by human behavior. All activities are by definition materially constituted; thus, given the plethora of ritual activities in every society worldwide, it is a physical impossibility that these diverse behaviors leave no archaeological traces. Acting on the basis of the traditional assumption, few traces were found, which only highlights the strength that theoretical assumptions may have over the formation of questions, methods, and data. As behavioralists began to look for evidence of ritual in object life histories, they found it everywhere. In well-documented archaeological contexts such as the pueblos of the American Southwest, it was evident that much time and energy went into the ritual construction, use, and disposal of ceremonial architecture as well as associated artifacts. It also became clear that, by relegating religion to the immaterial realm of ideology without pragmatic consequence rather than treating it as a kind of activity, archaeologists had assumed that ritual artifacts could be identified by default as nonutilitarian objects. Examination of known behavioral contexts such as ethnographies demonstrated that this was far too simplistic. Indeed, in the American Southwest, the houses of all nonpueblo peoples are central to ritual activities; moreover, everyday subsistence staples such as corn and water are the most revered ceremonial objects among many southwestern cultures. Finally, reuse is a critical factor in understanding their life histories, as many artifacts can move into and out of ritual contexts independently of our preconceived notions of utility. What appear to be old, even well-worn cooking pots and water jars are often used by Hopi peoples in their most sacred ceremonies.

Ritual and religious studies are just beginning to take advantage the material matrix. Recent ritual research (Walker 2008, 2009) has begun to combine study of performance characteristics, oral traditions, and interaction with nonhuman beings. Behavioral approaches to communication offer a useful model for integrating these facets of ritual studies.

Communication Studies

In one of the most innovative applications of behavioral archaeology, Schiffer and Miller (1999) designed an object-based model of communication. Typically communication studies focus on the transfer of information between two or more people and prioritize the intentions of the information senders. This move represents the height of common sense, but it fails to take advantage of, and indeed is actually undermined by, the complexity of the material matrix of behavior. Communication – like all other interactions – involves objects, and so an exclusive attention to people leaves out significant parts of the communicative process. What is more, although people may intend to send information, what is actually sent is only as real as what the receiver gets. Therefore, attending only to the sender's intent is fraught with problems. Also, much information is sent and received independently of conscious goals on either end.

Schiffer and Miller as behavioralists were aware of the limitations of conventional formulations based on prioritizing the sender's perspective and called attention to a symmetry between the process of communication and the process of archaeological inference. Archaeologists, after all, receive information about past peoples through interaction with artifacts. The process is often a lot slower than communication in everyday interactions, but they argue that the processes are analogous. Accordingly, they proposed a receiver-oriented approach to the study of communication in which artifacts as well as people are incorporated into the process. They developed a model composed of three information-related roles: senders, emitters, and receivers. In simple formulations similar to traditional "mediated" models of communication, one person (the sender) encodes or inscribes information through interaction with an artifact (the emitter), and from that artifact's subsequent performance, the receiver obtains information. This process of

communication would be tracked by studying how receivers reacted to information they gleaned in an interaction with the emitter. However, there is no reason to restrict communication to such a narrow range of possibilities. In theory, these roles could be played by any of the interactors. Thus, an artifact could, while interacting with a person, modify that person who would then nonverbally emit information to another person. A serrated knife (sender), for example, inscribes its signature in a mortal wound (emitter) that emits information to a forensic pathologist (receiver). Perhaps even more interesting is the possibility of passing information about the hidden world of supernatural entities. While the process is a material one, there is no reason that the information need be materially scientific. After all, how much information flowing through the material matrix has been so vetted? In many cultural contexts, evidence of the presence and intentions of witches, spirits, or other nonhuman agents are received regularly.

Future Directions

Behavioral archaeology has consistently fine-tuned its understanding of human behavior as the interaction of people with objects while simultaneously expanding its reach into the material matrix created by that behavior. Likely behavioralists will continue to study formation of archaeological deposits, technology, ritual, landscapes, communication, and social power. Behavioral archaeology like any productive program is constantly building and systematizing its assumptions and their implications for future research. In seeking to bring order to studies of a material matrix that by its very nature changes and moves through time, behavioralists find that a broad range of social and sensory performance characteristics remain only minimally integrated. Recent application of the synthetic model of inference to the study of communication has demonstrated that interactions between people and objects and the attendant performances of interactors highlight a logical equivalence between behavior and flows of information. This equivalence suggests that for some questions interactions are fruitfully studied as behaviors and for other questions as communicative processes. Likely behavioral archaeologists will continue to explore these and other symmetries as they push deeper into the material matrix of human object interactions.

Future directions in behavioral archaeology are only limited by a researcher's creativity in asking and answering behavioral questions about any human behavior in the material matrix. One area that should see much more attention is scientific activities, as practiced in any society. Discovery processes, for example, have been resistant to the generalizations of historians, philosophers, and social scientists. We suggest that a behavioral approach can make useful contributions because it is grounded in the people-artifact interactions that are the settings for discovery.

Béla Cserni

Csaba Szabó
University of Lucian Blaga Sibiu, Sibiu, Romania

Basic Biographical Information

Béla Cserni (1842–1916) is considered the first urban archaeologist of Transylvania (today Romania), the discoverer of one of the few preserved Roman gubernatorial palaces (*praetorium consularis*), and the founder of the first archaeological museum of Alba Iulia (Gyulafehérvár, Karlsburg). Born in the Habsburg Empire as a son of a Czech soldier and a Saxon mother in Hermannstadt (Sibiu, Nagyszeben), Cserni was raised in the Roman-Catholic orphanage, where he enriched his knowledge on local history, classical studies, and natural sciences too. In 1861 he moved to Alba Iulia, where he became a German teacher. Beside his pedagogic activity, he became a doctor in natural sciences in 1882 and a foremost specialist of the local flora and fauna of the region. After he witnessed the destruction of a large part of *Apulum*, the Roman city under Alba Iulia in 1864, Cserni's interest changed radically and formed consciously himself as a historian and scholar of antiquity. In 1886 the foundation of the Association of Historical, Archaeological and Natural Sciences of Fehér County marked also Cserni's life, who became the first librarian and museum keeper of the society. Due to his work and activity, the Association will open the first museum of Alba Iulia in 1888. This event marked also the beginning of the first systematic archaeological excavation in the city and the beginning of urban archaeology in Transylvania. As member of various scientific and cultural societies and associations in the Austro-Hungarian Empire, Béla Cserni built up an unusually rich academic network, which will help him in his endeavor as historian of the Roman city of Apulum. Having a rich correspondence with more than 30 renown scholars from all over Europe and visiting more than 50 museums, Béla Cserni relocated the Roman site of Apulum and the Transylvanian scholarship on an international scene. He died at 16 April 1916 in Alba Iulia (Gyulafehérvár, Karlsburg). His works and rich intellectual heritage was cited continuously by Hungarian and Romanian literature (often as Adalbert Cserni) during the twentieth century, but the contextualization of his importance among the European pioneers of archaeology begun just recently (Szabó 2016).

Major Accomplishments

Cserni's activity marked the fast development of museology and urban archaeology in Transylvania and, indirectly, Central Europe. His work in Alba Iulia represents the end of a four century long antiquarian tradition, marked by private collections and the first museums or institutions such as the Batthyaneum from Alba Iulia or the Brukenthal Collection from Sibiu. Cserni, as one of the numerous intellectuals of Europe, who specialized themselves in an autodidact way, became the first urban archaeologist of Transylvania, although less specialized as the best school of the region in that time, marked by the name of Béla Pósta and his team from Cluj (Kolozsvár).

Between 1888 and 1907 in 15 seasons, Cserni and his small team excavated the biggest Roman archaeological site (12,000 m^2) of that time in Central-East Europe. Although, he never recognized that he discovered the *praetorium consularis*, the palace of the governors of Dacia, his contribution in establishing the rules of urban archaeology in local context was essential (Bolindet et al. 2011; Schäfer 2014). Similarly, he was the first who identified the territory of the *Colonia Aurelia Apulensis* (today Partos, Alba Iulia, RO), the biggest Roman conurbation of Dacia, where he excavated numerous Roman houses, one of them being the first published in details from this city (Cserni 1912a, b). Among the two major sites, he excavated also the first identified Roman cemetery of the city and in numerous, non-Roman sites too.

His museum in less than two decades owned the biggest Roman collection in Central Europe, visited by numerous renown scholars of Europe.

Béla Cserni, Fig. 1 Béla Cserni, founder of urban archaeology in Transylvania. Source: Szabó (2016)

Publishing the first comprehensive synthesis on the archaeological finds of Apulum, Cserni published also the first topographic map of the Roman city (Cserni 1901).

Beside his rich activity as pioneer of urban archaeology, museology, and public archaeology, Cserni introduced also the photographic documentation in his work (Fig. 1).

Béla Pósta

Csaba Szabó
University of Lucian Blaga, Sibiu, Sibiu, Romania

Basic Biographical Information

Béla Pósta (22nd August, 1862–16th April, 1919) was the founder of the famous archaeological school from Cluj (Kolozsvár, Klausenburg) in Transylvania (today Romania). His school revolutionized not only the archaeological fieldworks but also professionalized the museology and the first archaeological departments of the Austro-Hungarian Empire (Petruț 2015, 167–168; Szabó 2016). Born in Kecskemét, he studied law in the Pázmány Péter University, but later the doyen of the golden age of Hungarian archaeology, Károly Torma, influenced him to change his interest toward the humanities and, especially, archaeology Banner (1962). In 1883 Pósta became trainee and later in 1895 museum-keeper in the Hungarian National Museum in Budapest (Vincze 2014, 21). His interests were focusing mostly on numismatics and the archaeology of the eighth to tenth century AD. During his numerous visits in foreign universities, he enriched his social and academic network and professionalized himself as an archaeologist and museologist too. From 1899 till his death, his activity is strictly related to his famous group and school from Cluj, Transylvania. Here, beside his activity as archaeologist and professor of newly founded university, Pósta became a prominent member of the local cultural and political elite and member of numerous cultural institutes and associations (Vincze 2014, 537–546). He died in

1919, a period which marked also the end of an era in the Transylvanian archaeology and ideology. His work and heritage was later transmitted and preserved by his students and friends and, recently, by the Pósta Béla Archaeological Association from Cluj-Napoca, Romania.

Major Accomplishments

The impact of Béla Pósta and his school was immense not only in Transylvania but, indirectly, in the whole Austro-Hungarian Empire. His school and activity emerged in a period, when the Austro-Hungarian Empire tried to find his imperial politics in the European and even world politics. The internal changes and infrastructural development of the region urged also the institutionalization and centralization of museums and the archaeological works and discipline as such. Following the archaeological methods and techniques of the most advanced German and Italian schools, the Hungarian scholars of the age of positivism created a still appreciable school in Central-East Europe.

Between 1899 and 1919, he and his team reorganized in Cluj the largest archaeological and numismatic collection, creating a pioneering model for modern museology in the region, later followed by numerous institutions in the region. In the same period, Pósta became professor of archaeology in the University of Cluj, where he revolutionized the discipline, creating a school which will give the first professional team of archaeologists of the next decades. Among his students we find renowned epigraphists and classical archaeologists, Árpád Buday, János Banner, and Sándor Ferenczi. They will continue Pósta's didactic work not only in the new political order of Romania but also in Hungary, keeping alive also the international relationships established by Pósta and his institution. From 1907, Béla Pósta served as the inspector of more than 30 museums and collections of the Hungarian part of the empire. Reorganizing the collections, he created the basics of the modern museology in Hungary and Transylvania too and centralized the financial and infrastructural system of museums of Central Europe. In the period of 1900–1915, Pósta and his team had 58 excavations in the Austro-Hungarian Empire; many of them – such as in Marosszentanna, Mezőbánd, Porolissum, and in the Roman Catholic Cathedral of Alba Iulia (Gyulafehérvár) – were groundbreaking discoveries of the period (Vincze 2014, 374–494). Pósta's rich correspondence with the great scholars and archaeologists of Europe proves his important role in the formation of the first, specialized and professionalized archaeologist in this part of the continent (Fig. 1).

Bell, Gertrude

Kate E. Riggs
Collection Services, Australian War Memorial, Canberra, ACT, Australia

Basic Biographical Information

Gertrude Margaret Lowthian Bell was born on 14 July 1868 in Washington Hall, County Durham, England. She came from a line of wealthy ironmasters. Her grandfather, Sir Isaac Lowthian Bell, and her father, Sir Hugh Bell, were heavily involved in politics. Her mother died when she was a young child, and she was brought up by her stepmother Dame Florence Bell, who was a playwright and author.

Gertrude Bell's early education was at Queen's College in London. She enrolled at Lady Margaret Hall, Oxford University in 1886. She specialized in modern history, becoming the first woman to earn a first-class degree in the subject. She was not formally trained in archaeology, aside from a few weeks spent with Dr. David Hogarth in Greece while on holiday in 1898 (Burgoyne 1958; Winstone 1978). The beginning of her lifelong passion for the Middle East can be traced to a visit in 1892 to her uncle, who was an ambassador serving in Tehran, Iran (Winstone 1978). In 1899, she began a period of sustained travel in Asia, Europe, Mesopotamia, and Arabia. She became fluent in Arabic, Turkish, and Persian and wrote of her experiences in five works that were published in the two decades preceding the First World War (Howell 2006). During this war, Gertrude Bell worked as a spy for the British Government gathering information on Turkish railways and forming alliances with Arab tribes, alongside T.E. Lawrence. Following the British capture of Baghdad in 1917, Bell became heavily involved with the political reinvention of Mesopotamia due to her understanding of the area and fluency in the language. Bell was a passionate believer in Arab independence and assisted in setting up infrastructure and installing ruler Faisal I as monarch of Iraq (Burgoyne 1958).

Major Accomplishments

Gertrude Bell's career focused on the archaeology of Greater Syria, Mesopotamia, Asia Minor, and Arabia. Her major accomplishments in archaeology include scholarly publications on Byzantine monuments in Asia Minor, the establishment of legislation and methods that significantly improved the protection of cultural heritage in Iraq, and establishment of the National Museum of Iraq. However, she is perhaps best known for her role in developing the political borders in the Middle East after the First World War, particularly those of Jordan and Iraq.

In her own words, Gertrude Bell considered herself "nothing better than an antiquarian at heart" (Bell 1927). However, many of her scholarly works on Byzantine monuments in Asia Minor are still considered the standard works on the subject (Howell 2006). Bell conducted several surveys over the course of her travels, especially during her 1905 trip to western Syria and Anatolia (Lawler 2008). Chief among these surveys was her work at Binbirkilise, with the resulting book completed with Sir William Ramsay considered "one of the most enduring works of scholarship" of the area (Ousterhout and Jackson 2008: ix). Bell's book *The Palace and Mosque at Ukhaidir* (1914) is considered by some to be "her most important contribution to archaeology" (Lukitz 2006).

One of Bell's major contributions to archaeology is the early development of practical methods for a government to work with archaeologists to protect a country's cultural heritage. She played an eminent role in setting up the necessary infrastructure needed for serious and scholarly excavation rather than the treasure hunting and amateur

excavation seen in the Middle East before the First World War. The stable political climate in Iraq that existed at that time brought renewed interest from archaeologists to conduct excavations in Iraq. Responding to a need for updated antiquities legislation, Bell began writing a Law of Excavations, which was enacted at the end of 1922 (Bell 1927). The progressive attitude of these laws and their favorable conditions for archaeologists allowed the development of new techniques and new methods of excavation. In this way, Bell's work is still relevant and influential on younger generations of archaeologists.

Gertrude Bell pioneered the idea of retaining antiquities in their country of origin rather than transporting them to European museums or collections. In 1926, she established the National Museum of Iraq, which held one of the world's greatest collections of Mesopotamian antiquities prior to the 2003 invasion by the United States and its allies (Wallach 1996; Lawler 2008). Driven by her love of the country, Bell became Iraq's Honorary Director of Antiquities in 1922. She dedicated the last years of her life to developing Iraqi national identity through ownership of its cultural heritage (Winstone 1978). To implement this, Bell traveled to archaeological sites at the end of each excavation season to divide the finds between the archaeologist and Iraq (Winstone 1978). She also traveled to places where local people were undertaking their own excavations and bought any significant finds (Bell 1927). She left behind a competent record of archaeological sites, including a highly valuable photo record of 7000 photos, taken between 1900 and 1918.

Gertrude Bell is lauded today as a pioneering woman in archaeology. It is somewhat ironic, then, that she opposed the right of women to vote, contending that women were not ready to vote while they remained confined to the domestic sphere (Bell 1927). This may be due in part to the influence of her stepmother, Dame Florence Bell, who encouraged her involvement in the intellectual activities of the Anti-Suffrage League (O'Brien 2000). Yet Gertrude Bell's commitment to education and female betterment was still demonstrated through her dedicated promotion of the education of Iraqi women.

The times in which Gertrude Bell practiced archaeology were vastly different from those of the modern day. She practiced during a period when the British Empire held great sway over much of the wider world and when archaeology was practiced as an eccentric oddity, with little external account ability. Archaeologists of the time were yet to embrace the scientific approaches of "new archaeology" or address the politics of cultural ownership, a matter which is so pressing today. Gertrude Bell excelled in both areas: her thoroughness and attention to detail were congruent with the tenets of scientific archaeology; and her political awareness, respect for people whose cultures she studied, and support for repatriation and self-rule is a model for postcolonial archaeology today. Beyond this, Gertrude Bell was a role model for the archaeologist as hero – feminist hero.

Beltrán Martínez, Antonio

Pilar Utrilla
Departamento de Ciencias de la Antigüedad, University of Zaragoza, Zaragoza, Spain

Beltrán Martínez, Antonio, Fig. 1 A. Beltran (aged 82)

Basic Biographical Information

Antonio Beltrán Martínez became professor at the Department of Archaeology, Epigraphy and Numismatics at the University of Zaragoza in 1949, the place from which he worked most of his academic life. For 60 years and with a clear mind until the very end, he was a prolific university lecturer, manager, and researcher, while at the same time, he was an excellent communicator with an incredible ability to maintain the interest of all kinds of audiences, academic as well as general public. He inspired the creation of publications, museums, and cultural parks and organized 27 archaeology conferences. He founded the series of archaeological monographs for the University of Zaragoza, where he published the majority of his books. Among many other honors, he was named the city's official Chronicler, and he was awarded the Aragón Award. Author of more than a 100 books and more than a 1,000 articles (367 on rock art), he was a true scholar with a knowledge so encyclopedic that he could write numismatics handbooks as well as speak about the food culture of Aragón, the typical dress, or the local patron saint.

However, what made him truly happy was the study of rock art, the subject to which he dedicated his later research career and which brought him international recognition. He was member of the International Rock Art Committee (ICOMOS), represented Spain in the International Union of Prehistoric and Protohistoric Sciences (IUPPS), and chaired the ninth Commission of Prehistoric Art. He travelled wherever there was rock art, like Kakadu National Park in Australia, Serra da Capivara in Brazil, and the paintings in Namibia. He collaborated in the defense of the Portuguese rock art site at Foz Coa. He was always ready to go to the most inaccessible caves, like Los Estrechos in Albalate where, at almost 80 years of age, he rope climbed to study the schematic paintings (Figs. 1, 2, and 3).

Major Accomplishments

A brief itinerary of his work relating to rock art can be divided into two distinct stages:

1. From 1966 to 1988: Fieldwork outside of Aragón: he studied various Paleolithic caves in the French Pyrenees, and he travelled all the Spanish east coast studying post-Paleolithic art and travelled to the Canary Islands to study its engravings and paintings. Among his publications, three archaeological monographs about Paleolithic art stand out (Le Portel, 1966; Bedeilhac, 1968 y Niaux, 1973), five more about the Levantine rock art (1969: los Grajos; 1970: Valdelcharco; 1972: Cañaíca del Calar y Fuente del Sabuco; 1976: La Sarga; 1988: Peña Rubia) or schematic art (1972: Lecina), and two books about the rock art of the Canary Islands (Barranco de Balos, 1971; Gáldar, 1973). His book of synthesis *Arte Rupestre*

Beltrán Martínez, Antonio, Fig. 2 A. Beltran (aged 75) climbing up a ladder to take photographs of the schematic rock paintings of Los Estrechos (Albalate del Arzobispo, Spain)

Levantino (Levantine rock art) (Zaragoza, 1968) provided a global vision about the geographical location, technique, and themes and approached the problem with chronology advocating the most popular sequence, from the most naturalistic to the most schematic, theory that years later he himself would question. He published Italian versions in Milan like *Da cacciatori ad allevatori: l'arte rupestre del Levante spagnolo* (1980) and *Arte rupestre preistorica* (1993), which were also translated into English and French.

2. From 1989 to 2006: At the age of 60, he focused only on Aragón and began doubting his own chronological system. In his book of synthesis *Arte prehistórico en Aragón* (1993) (*Prehistoric Art in Aragón*), he includes surprising results about the chronology of schematic art. This versatile style that he believed to be typical of the Bronze Age acquired an apparent great antiquity with the appearance of geometric figures at Riparo Villabruna, similar to those from Chaparros site, located below "open-legged" Levantine motifs, which brought him to speak of a continuity since the end of Paleolithic art. On the other hand, the appearance of the sealed figures

Beltrán Martínez, Antonio, Fig. 3 A. Beltrán (aged 90) presides his last Ph.D. jury in the University of Zaragoza

of Porto Badisco (Port Badisco) or the discovery of the Petracos style in Alicante forced him to outline the Neolithic chronology and to distinguish the semi-naturalist from the purely schematic.

Although he studied the schematic paintings of Estadilla in Huesca (1989), he focused with great eagerness on Bajo Aragón (lower Aragón, Teruel) where he led the creation of Río Martín's Cultural Park, the place he was most fond of. He dedicated his last eight monographs to the Levantine rock art sites located within this park (1994: La Higuera; 1995: Tía Chula y Cañada de Marco; 1989 and 1997: Los Chaparros y los Estrechos de Albalate; 1998: El Mortero; 2000: Garroso; 2002: Valdelcharco; 2005: Cerro Felío). In 2005 he finally published a complete catalogue of Río Martín. The impatient octogenarian seemed to want to quickly wrap up his knowledge before taking his final breath, which he did few months later, at 90 years of age.

Berenguer, José

Carole Sinclaire-Aguirre
Curator Department, Museo Chileno de Arte Precolombino, Santiago, Region Metropolitana, Chile

Basic Biographical Information

José Berenguer obtained his licentiate degree in prehistory and archaeology from the Universidad de Chile (UCH) in 1975 and his Ph.D. in Anthropology from the University of Illinois at Urbana-Champaign in 2002. He had begun his higher education as a geography major at UCH in 1971 but was unable to complete that program owing to the military coup that occurred in Chile in 1973. However, he credits those early studies with instilling a certain geographical orientation in his research. Dr. Berenguer served as professor in UCH's Department of Anthropology from 1978 to 1982 and from 1992 to 1999. In 1979, he worked as an investigator at the Instituto Otavaleño de Antropología in Ecuador. He is currently head curator at the Museo Chileno de Arte

Precolombino (www.precolombino.cl), where he has curated approximately 30 exhibitions, edited more than 20 exhibit catalogs, and served as editor in chief of the institution's scientific journal for more than three decades (www.boletinmuseoprecolombino.cl). He served three terms as director of the Sociedad Chilena de Arqueología and two terms as editor of that organization's scholarly journal and has been a member of the Archaeology and Anthropology Research Group of the National Science and Technology Development Fund (FONDECYT). He also served a consultant for the nomination of the Inka Road/*Qhapaq Ñan* to UNESCO's list of World Heritage sites. Since 1984, he has obtained a variety of research grants from organizations such as the Wenner-Gren Foundation, the Tinker Foundation, Chile's National Science and Technology Fund (FONDECYT), and the country's National Fund for Cultural Development and the Arts (FONDART). A selection of his leading publications is available on ResearchGate and Academia.edu.

Major Accomplishments

Dr. Berenguer began his professional career as part of the "Toconce Group," an interdisciplinary team that was formed in 1977 to conduct research in the interior of Northern Chile's Antofagasta Region. The group's distinctive approach included involving local indigenous communities in their work and employing indigenous knowledge to further their understanding of the pre-Hispanic past – an approach that has influenced later generations of archaeologists in Chile. One of the group's most important, albeit largely unrecognized, contributions was to lay the foundations for an "archaeology of ritual" that extended beyond funerary rites – a groundbreaking approach in the field at that time. The group's studies on ritual activity in the *chullpas* (funerary towers) of Toconce and the link between those structures and local sacred geography are still considered seminal works on the topic.

One of Dr. Berenguer's current lines of investigation examines the rock art of the Atacama Desert. Aware that rock art can only be incorporated into prehistoric studies when situated chronologically, he has led an unprecedented effort to build a master sequence for the Loa River rock art styles (Berenguer et al. 1985), an initiative that is being continued by more recent investigators in Northern Chile. One of his most important works focuses on the rock art of Taira, in the upper Loa Valley. Contrary to conventional approaches of the time – which were marked by the understandable rejection of the importance and use of ethnographic analogies in interpreting European paleolithic art, along with the not always justified extrapolation of those limitations to other forms of rock art studies around the globe – in the mid-1980s, he interpreted the images found at Taira in relation to the multiplication and conservation of livestock herds, basing this interpretation on the cosmogenies of present-day Andean herding communities, historic documents, and detailed analysis of the images themselves (Berenguer and Martínez 1986). Dr. Berenguer has also proposed that the natural environment is yet another signifier in the message conveyed by those images and that no study of rock art should fail to take geography into account. In another contravention of the prevailing orthodoxy, on the basis of Andean ethnography, in the mid-1990s, Dr. Berenguer proposed that the Taira images are icons with agency, a kind of ritual "symbolic work" (Berenguer 1995).

A parallel line of investigation examines the Tiwanaku presence in Northern Chile. From Dr. Berenguer's perspective, the presence of Tiwanaku materials in Northern Chile indicates that an extensive sphere of interaction had been established. For close to 30 years, his comprehensive work on this topic (Berenguer and Dauelsberg 1989) has provided other researchers with an inexhaustible source of hypotheses to test. Indeed, his expertise in the archaeology of the image has led him to identify snuff tablets for hallucinogenic substances in the hands of well-known Tiwanaku statues. Given the prevalence of certain representations – individuals in a state of trance, snuff tablets, and other elements of the psychotropic complex – in the art of that Altiplano society, Dr. Berenguer concludes that Tiwanaku was a state with a strong shamanic component. Following from this, he postulates that the images

were part of an iconography of power that circulated selectively in the Tiwanaku sphere by means of icon objects related to the consumption of visionary plants (Berenguer 1998).

Yet another of his lines of research, which has emerged from the museum exhibitions he has curated, focuses on the headdresses of the Atacama Desert. As in his previous work with rock art styles and his later work on the San Pedro de Atacama cultural sequence, here Dr. Berenguer organized the headdresses into a timeline before investigating their role as markers or diacritics of social interaction, in addition to studying their designs and uses (Berenguer 2006). He interprets dome-shaped headdresses, for example, as combat helmets, which prompts him to question the local tendency to deny knowledge of conflicts in the pre-Hispanic past. In fact, Berenguer does not believe that the pre-Hispanic exchange networks of the South-Central Andes would have required a climate of "social harmony," as other investigators have proposed – a hypothesis that he views as functionalist and hardly compatible with human nature (Berenguer 2002).

Dr. Berenguer's doctoral research advanced the prevailing models of caravan traffic for the South-Central Andes and made him an immediate authority on that kind of traffic, interregional interaction, and roadway archaeology (Berenguer 2002). His approach articulated several kinds of evidence – from small settlements, trails of llama caravans, traveler's rites, and rock art. One of his most innovative contributions to the study of that traffic was his investigation into internodal spaces or zones *between* population hubs. An interesting application of that approach is found in his study of the Inca road network in Northern Chile. Having noted that local archaeologists commonly studied elements such as roads, settlements, high-altitude shrines, and mining and metallurgical operations separately, Berenguer approached his investigation of the *Qhapaq Ñan* from a comprehensive perspective that incorporated all of these different components (Berenguer 2007). Along the same lines, one of his recent regional analyses brings together information analyzed separately by other researchers in order to characterize the Inca model in Antofagasta Region as one of productive clusters and extractive enclaves (Berenguer and Salazar 2017).

Berenguer is convinced that archaeological study should include the recent past and even the present, and he has had the opportunity to reaffirm this conviction in forensic archaeology work related to the search for and exhumation of the remains of individuals "disappeared" and assassinated for political motives during Chile's military dictatorship. A major hallmark of Berenguer's career as an archaeologist, and one that is closely linked to his activities as a museum curator, is his commitment to the dissemination of scientific information to the public. In Chile, this kind of linkage between scholars and the broader society is only just beginning to be valued in the career of a scientist, particularly because of the social role that all knowledge production must have. Today, Dr. Berenguer's main aim is to expand our understanding of the visual cultures of pre-Hispanic desert societies. As a proponent of realist theory in archaeology, for Berenguer, it is not enough to identify patterns and events in images; one also has to discover the social structures and practices that lie behind those images, and he has applied this approach also to understanding the Middle (Berenguer 1998) and Late (Berenguer and Salazar 2017) Horizons in pre-Hispanic Northern Chile.

Overall, Berenguer believes his greatest contribution cannot be found in the results and findings of his investigations but in the ideas that have emerged from them, ideas that have been and continue to be discussed and tested by researchers in different fields. What's important says Berenguer is not that they think we're right but that our ideas make them think and drive them to make their own contribution to furthering the archaeological study of human societies.

Berenike, Archaeology of

Steven E. Sidebotham
History Department, University of Delaware, Newark, DE, USA

Introduction

Ptolemy II Philadelphus founded the Egyptian Red Sea emporium of Berenike (23° 54.62′ N/35° 28.42′ E) in c. 275 BCE naming it after his mother. Berenike, approximately 825 km south southeast of Suez and about 260 km east of Aswan, was the southernmost Red Sea emporium in Ptolemaic and Roman Egypt (Fig. 1). This entrepôt functioned for approximately eight centuries until peacefully abandoned sometime before the mid-sixth century CE for unknown reasons. Creating this settlement was part of a larger Ptolemaic infrastructure project, which included (re)excavating a Nile-Red Sea canal (termini at/near Bubastis in the delta-near Klysma/Suez in the pre-Roman era; at Babylon opposite Fayum-near Klysma/Suez in Roman times) and establishing other ports along the Red Sea coast, both in Egypt and farther south on the African littoral. Ptolemaic authorities also built roads, forts, and unfortified watering stations in the Eastern Desert of Egypt linking Red Sea ports to counterparts on the Nile and joining emporia on the Nile and Red Sea to mining settlements. At the latter the Ptolemies sought primarily gold and amethysts (Sidebotham et al. 2008; Sidebotham 2011).

The Romans increased exploitation of mineral wealth in the Eastern Desert (beryls/emeralds, amethysts, gold, copper, and hard stone, including marble, for buildings, sarcophagi, and statuary). Many, if not all, of these endeavors were government sponsored. The Romans enlarged Red Sea ports in Egypt and expanded the highway system in the Eastern Desert. The Romans also renovated/extended old roads and constructed new ones. Along these thoroughfares, the Romans constructed additional watering points, *praesidia* (forts), *skopeloi* (watch and signal towers), and other infrastructure. Roads in the Eastern Desert in both Ptolemaic and Roman times consisted primarily of cleared tracks of varying widths with surface debris pushed to the edges forming windrows in many cases. Some roads, both primary and those within or leading to quarries and mines, were artificially elevated to facilitate passage across difficult terrain. Primary means of transport were camels, donkeys, and horses. There was also human pedestrian traffic and wheeled conveyances used within quarry and mining settlements. Route-marking cairns of varying sizes were built of locally acquired stone, and graves lined many of these desert tracks; none of the highways appears to have been paved, and few, if any, milestones were erected (Sidebotham 2011).

Berenike, Archaeology of, Fig. 1 Map of the region (M. Hense)

G.B. Belzoni (re)discovered Berenike in 1818, and throughout the nineteenth and early twentieth centuries, European visitors (including J.G. Wilkinson, J.R. Wellsted, H. Barth, E.S. Purdy, R.E Colston, W. Golénischeff, E.A. Floyer, and T. Bent, among others) conducted cursory examinations and cleared portions of the so-called Serapis Temple (now named the Great Temple) on the highest part and near the center of the site. The current project, 1994–2001 (University of Delaware, USA; Leiden University, the Netherlands/UCLA) and 2008–present (University of Delaware-Polish Centre of Mediterranean Archaeology, University of Warsaw), has undertaken systematic, scientific surveys, geological coring, geomagnetic examination, excavations, documentation of a broad array of finds (ecofacts and artifacts both organic and inorganic), and extensive publication (Fig. 2) (Sidebotham 2011, 2017, 2018; Sidebotham and Wendrich 1995, 1996, 1998a, b, 1999, 2000, 2001-2002, 2007; Sidebotham and Zych 2010, 2011, 2012, 2016; Zych et al. 2016).

The ruins of Berenike cover approximately 28.5 ha with a maximum east-west length of about 700 × 400 m (in one area an additional 5000 m^2) north-south. Geological coring combined with studies of seismic and tectonic activities in the Red Sea in general indicates sea-level

Berenike, Archaeology of, Fig. 2 The site plan (M. Hense)

changes over the past two millennia; inflow of sediments via wadis debouching into the Red Sea immediately north and south of Berenike resulted in silting of the northern, southern, and southwestern harbors. The ancient inhabitants made no attempt, apparently, to dredge (as contrasted with Myos Hormos, a Ptolemaic-Roman port c. 300 km north of Berenike) to keep the harbors operational; instead, due to progradation of the coastline, residents moved the settlement ever eastward. Excavations thus far have shown that the Ptolemaic settlement lay farthest west, the early Roman community was east of that, and the late Roman city lay the farthest east of all (Figs. 2 and 3). Of course, there is some overlap of portions of later periods of occupation atop earlier ones (Sidebotham 2011).

Archaeological evidence indicates three peak periods at Berenike: early-middle Ptolemaic (mid-third to mid-second centuries BCE), early Roman (first to early second century CE), and late Roman (mid-fourth through fifth centuries CE). There was, apparently, a mini-renaissance in the late second and early third centuries CE (the Severan period). These were interspersed with nadirs (late Ptolemaic, second-first centuries BCE; middle Roman, much of the second to fourth centuries CE; and later Roman, mid-late

Berenike, Archaeology of, Fig. 3 The geomagnetic survey map (Survey by D. Święch and R. Ryndziewicz. Processed by T.M. Herbich)

fifth to mid-sixth centuries CE) until abandonment sometime before the mid-sixth century CE.

Definition

Ptolemaic Era

Initially, Berenike's raisons d'être were to meet the needs of the Ptolemaic government and military: importation of elephants (likely either the bush, *Loxodonta africana*, or forest, *Loxodonta cyclotis*, species) for military use, gold, and ivory. Some merchandise for civilian consumption and conveyed by private entrepreneurs also passed through Berenike on which the government levied substantial taxes. In Ptolemaic times Berenike was in contact mainly with other areas of Egypt, Nilotic and Red Sea coastal Africa, and the eastern Mediterranean/Levant. There were diplomatic exchanges between Ptolemaic Egypt and Aśoka, the Mauryan king of India, in the third century BCE and some contact with southern Arabia. A road across the Eastern Desert linked Berenike to (Contra)Apollonopolis Magna (modern Edfu) on the Nile c. 340 km to the northwest (Sidebotham 2011).

Ptolemaic areas of Berenike lay primarily in the western part of the site, also some in the northern and central portions, and included zones for manufacturing activities (brick making, the production of lead, copper alloy, iron, creation of small-scale sculpture), a ditch (possibly for retaining elephants), and remains of a tower and other fortification walls, which had been badly robbed in the Augustan era. These fortifications indicate military presence in the early Ptolemaic era and are rare examples of Hellenistic urban defenses found anywhere in Egypt. A rectangular-shaped excavation into bedrock in Ptolemaic times immediately behind some of the fortifications contained five tunnels, one of which was hydraulic; incomplete excavations prohibit identification of four of these features (Sidebotham and Zych 2016). There are human skeletons

deposited at some unknown date in antiquity atop some of the Ptolemaic ruins. Some of these human remains preserved evidence of immediate post-mortem disturbance with extremities gnawed by scavengers. Ptolemaic trash deposits lay north of the southwestern-most harbor. Ptolemaic-era building materials include gypsum/anhydrite, limestone, and assorted stones. Fired brick appears in a section of a cistern from this era; this material is not evident in other excavated structures on the site though individual loose fired bricks appear throughout the archaeological record in the Roman period (see *infra*).

Artifacts and ecofacts (Faunal and Floral remains) from the Ptolemaic era include amphora sherds from Rhodes, Knidos, and other areas of the Aegean (some with stamped handles: mainly from Rhodes); fine wares from Campania and Rhodes; fragments of lead sheets; some preserving holes for sheathing ships' hulls; copper alloy and iron nails and tacks; some sculpture; beads; an intaglio, likely depicting a deity; ostraka written in Demotic; burned industrial waste; and some organic remains (faunal, botanical, basketry, cordage, matting). There are also some Ptolemaic silver and *aes* coins. Excavations in an early Ptolemaic trash deposit documented a broken faience scarab-heirloom with a hieroglyphic text from the tenth century BCE (twenty-first Dynasty Pharaoh Siamun). Faunal analysis – including the presence of camel and pig – indicates mainly an Egyptian and desert dwelling population in Berenike at this time (Sidebotham 2018).

Contemporary records reveal great interest in the Red Sea during the reign of Ptolemy VIII (r. 169–116 BCE) as the creation of an official at this time, though possibly later, styled the *strategos kai epistrategos tes Erythras kai Indikes Thalassas* indicates. These together with a text of the same monarch from the main temple at Berenike suggest it was during his reign that the Great Temple, initially found and partially cleared by Belzoni, and which he identified as a temple to Serapis, was constructed. The top of a broken stele depicting traditional Egyptian deities excavated in the Great Temple appears to be of Ptolemaic date. The era of Ptolemy VI–VIII (180–116 BCE) was one of extensive temple construction elsewhere in Egypt. Strabo (2.3.4) reported toward the end of his reign that Ptolemy VIII sponsored Eudoxus of Cyzicus to explore the Red Sea and Indian Ocean. This passage corroborates other sources that record official (and, likely private entrepreneurial) interest in those regions at that time (Sidebotham and Zych 2016).

Early Roman Era

Roman (30 BCE to mid-sixth century CE) activities at Berenike were more commercial and civilian in nature than under the Ptolemies, though the Roman military was present especially in the early Roman period. The volume of trade also increased. During the Roman occupation Berenike's networks expanded geographically throughout much of the Mediterranean basin. In early Roman times, these stretched as far west as Gaul, the Iberian Peninsula, and Mauretania (Morocco) and at least as far east as India and Sri Lanka on a regular basis. Interaction with the Persian Gulf was minimal and indirect via emporia in southern Arabia (e.g., Sumhuram/Moscha Limen, Qana'). Ships traveling between India and the Red Sea also stopped at these and other south Arabian ports, for example, the island of Socotra. There appears to have been little exchange between Berenike and the Indian Ocean coast of Africa. At this time Berenike was one conduit in a network that included routes (intra-Mediterranean, trans-Saharan, Amber, trans-Arabian, and so-called Silk) linking portions of Africa, Asia, and Europe together. There are numerous ancient literary references to Berenike and its importance in the commerce of this era (e.g., Strabo, Pliny the Elder, *Periplus Maris Erythraei*). The Roman government reaped a handsome income from taxes and tolls levied on merchandise imported from outside the empire. The government also profited from the transport of products, people, and animals across the Eastern Desert. Documents recording these levies are evident from the first and second centuries CE and include the Koptos Tariff (May 90 CE) and the so-called Muziris Papyrus (mid-second century CE). In the Roman period, the main thoroughfare connected Berenike to the Nile emporium of

Koptos (modern Quft), c. 381 km to the northwest [north of (Contra)Apollonopolis Magna/Edfu].

Early Roman remains at Berenike comprise portions wharfs and quay walls beneath later Roman edifices on the eastern edge of the site. Early Roman structures also appear in the southwestern harbor with putative wharfs/quays and other unidentifiable features including a sunken rectilinear-shaped one made of white gypsum/anhydrite ashlars. The appearance and method of construction of the latter closely resemble those of the Great Temple at the topmost part of the city, which may be Ptolemaic or early Roman in its original construction. This may suggest a chronological as well as functional relationship between the Great Temple and this enigmatic sunken structure. One theory proposes that the sunken feature was a Red Sea version of a Nilometer (Zych et al. 2011; Sidebotham and Zych 2012; Sidebotham 2014). There are early Roman (mainly second and third quarters of the first century CE) rubbish deposits north of the city, which have produced numerous ostraka, papyri, stamped and painted jar stoppers, other organic and inorganic remains, and floral and faunal ecofacts. There are also edifices in the city center (Great Temple and associated structures). The latter include small-scale industrial facilities and structures of unknown function. The scant remains of early Roman-era structures thus far excavated indicate construction from limestone boulders and gypsum/anhydrite ashlars quarried from nearby sources. Excavations also documented fragments of window pane glass from early Roman contexts suggesting that the apertures of some structures from this era had glass fittings.

Early Roman period finds include extensive organic and inorganic remains of artifacts and ecofacts mainly, but not exclusively, from the early Roman rubbish deposits north of the city (as noted *supra*) (Cappers 2006; Zieliński 2011). Most written documents from the site date from this era (ostraka, papyri, inscriptions on stone and dipinti on wood and shell, and stamped and/or painted plaster jar stoppers). Most ostraka are public documents, while the majority of papyri detail private affairs though one of the latter is a literary papyrus containing references to the rites of Cybele (Ast and Lougovaya 2015). One ostraka archive contains information on activities at the Roman customs house/customs gate in the city at this time (first century CE), while another deals with the army's involvement in the transport and procurement of fresh water for Berenike (also first century CE) (Bagnall et al. 2000, 2005; Ast and Bagnall 2016). Quantitatively, most identifiable coins found from all phases of site occupation (both billion and *aes*) also date from this era. Finds from the southwestern harbor include ship timbers and a ship's frame made of cedar wood, rigging, lead hull sheathing, brailing rings made of wood and animal horn, and ships' ballast comprising vesicular basalt imported from Qana' on the Indian Ocean coast of southern Arabia (Sidebotham 2008, 2011). There was also redeposited industrial waste, stone – including large amounts of imported obsidian – sard, selenite, beryl, worked turtle and mother-of-pearl shell, leather, and cordage, and evidence of extensive patching and recycling of various qualities of textiles and cloth. There are extensive burned deposits: possible evidence of charcoal manufacture using discarded ships' timbers or evidence for an extensive and accidental fire that swept through the southwestern harbor sometime in the first or second century CE. The population at this time came from throughout the Mediterranean basin (Europe, North Africa, Middle East), Egypt, the Red Sea, and Indian Ocean littorals.

In early Roman times and later, there was military presence both at the port and in *praesidia* (Forts) in the environs. Ten *praesidia*, ranging from southwest to northwest of the city and varying from c. 7 km to about 25 km distant, protected approaches to Berenike in the early Roman period. Some of these installations witnessed Ptolemaic occupation and later Roman use as well. Several hundred early Roman-era ostraka from the trash dump north of the city center (noted *supra*) indicate that the Roman army secured, transported, and distributed potable water likely from some *praesidia* closest to Berenike (viz., Siket and two in Wadi Kalalat) for consumption in the city and, perhaps, for use aboard outbound ships (Sidebotham 2011). Military and police units also guarded/patrolled the route between

Berenike and the Nile at Koptos and some of the mines (notably beryl/emerald and likely gold) in the region. Some soldiers were regular Roman military, while others were auxiliaries (including Palmyrene mounted troops in at least the late second and early third century CE) (Sidebotham et al. 2008).

Late Roman Era

In the late Roman period, ceramic and numismatic evidence indicates that Berenike's network contracted in the north and west to include primarily the eastern Mediterranean/Levant; contacts between Berenike and other areas of the Red Sea-Indian Ocean basin including south Asia (India and Sri Lanka; there is also a bead from Jatim in eastern Java and possibly specimens from Vietnam and/or Thailand) remained extensive. The main Nile terminus for the late Roman-era road lay, as in early Roman times, at Koptos. The latest literary reference to Berenike is in 524/525 CE in the *Martyrium Sancti Arethae* (27–29), but the port had clearly declined in importance by that time. By the mid-sixth century, Berenike lay abandoned due, perhaps, to continued harbor silting, a plague (bubonic), which Procopius mentions passing through the region and/or increased competition from south Arabian, Axumite, and other middlemen. There is no evidence of Islamic occupation. Recent excavations in the Great Temple recorded three fragments of a Middle Kingdom (eighteenth century BCE) stele of the Pharaoh Amenemhet IV. These may join with one Belzoni recovered from the temple, but which is now lost. These fragments may indicate the presence of a roadstead here at that time, which supported communications between Saww (in Wadi Gawasis on the coast ca. 350 km north of Berenike) and Punt (Hense at al. 2015).

The bulk of the visible remains at the eastern edge and central parts of the site, but also somewhat in the southwestern harbor, are late Roman structures (mid-fourth into the fifth century CE) though these lay, in some instances, at least, above earlier remains. These late Roman structures were built primarily of fossilized coral heads; these buildings have quoins, staircases, and some thresholds made from recycled gypsum/anhydrite ashlars – including at least one bilingual (Greek-Latin) inscription built into a wall – recovered from earlier edifices. Three other first- and early second-century CE inscriptions found in the courtyard of a multistoried structure of late Roman date, and likely taken from the Great Temple, which lay just to the west, seem to have also been destined for recycling into late Roman structures in the central-eastern part of Berenike. Teak and cedar wood timbers, likely recycled from dismantled ships, often appear as supports built horizontally into fossilized coral head walls or forming partial roofing or shelving for buildings in this period. Recycling of wooden ship parts into architecture had a long tradition in Egypt dating back thousands of years (Sidebotham 2008, 2014; Sidebotham and Zych 2016). Excavations have documented a few fired bricks with plaster adhering suggesting the presence of some hydraulic facility that has yet to be identified. These together with the recovery of fragments of some glass bath flasks may point to the presence of a bath somewhere in the city that has yet to be identified.

Structures in the central and eastern parts of the site comprise cult centers, small-scale industrial areas, multistoried commercial-residential buildings, and trash dumps; the latter were deposited atop, inside, and outside of abandoned buildings. In the southwestern harbor are remains of a late fourth to fifth century CE temple adjacent to a sunken structure of unknown function built of white gypsum/anhydrite ashlars (described *supra*). This late Roman harbor temple seems to have accommodated several cults, both Greco-Roman, Egyptian, southern Arabian and, perhaps, Nubian/Meroitic (Rądkowska et al. 2010; Sidebotham et al. 2015; Sidebotham 2014). The only formal necropolis thus far identified in/near the city seems to date from at least the late Roman era. In addition, hundreds of late Roman-era tombs lay atop low hills situated west/west southwest of Berenike; most of these have been robbed at some unknown date. Early Roman burials with grave goods have been documented near the Ptolemaic hydraulic feature (noted above). There are also early and middle Roman-era tombs in the abandoned modern military bunker area northwest of the city.

Late Roman-era finds include many botanical and faunal remains, both organic and inorganic artifacts (especially ceramics, textiles – some imported from India – basketry, matting and cordage, glass, beads, industrial waste, and coins). Late Roman (mainly after the mid-fourth century CE) *aes* coins, primarily of the smaller denominations, are the second most abundant on site (after the early Roman issues).

A few non-Roman coins also date from this era: an issue of Axumite King Aphilas (c. 270/290–before 330 CE), a second century CE Satavahana coin, a silver example of Rudrasena III of the Kshatrapa dynasty in India (dating 362 CE) (Sidebotham and Wendrich 2007) and a few, apparently, barbarous *aes* specimens of unknown provenance. The few written (non-numismatic) documents from this era of the city's history comprise laconic dipinti and graffiti on sherds, one of which is written in Aramaic or Hebrew. The population was primarily Egyptian (both desert dwelling and marine oriented based on faunal analysis of items they consumed) though there is evidence of contact with and, perhaps, people from Axum, southern Arabia, and the Indian subcontinent/Sri Lanka who were trading with, passing through, or dwelling in the city at that time.

Key Issues/Current Debates

General Observations

Berenike was very cosmopolitan. Twelve different written languages (European, African, and Asian), a variety of religious practices, and an array of floral and faunal remains (a reflection of diet and, often, ethnicity) as well as finer ceramics indicate the presence of diverse groups of men, women, and children, as do burial practices/skeletal remains. Texts recorded on stone document that some women played a prominent role in the life of the city, at least in early Roman times. Remains of an animal necropolis indicate that cats and kittens, dogs, and puppies as well as baboons and vervet or grivet monkeys were among some of the pets of the residents in the early Roman era. A few of the animal remains preserved iron collars, one of which had been decorated with beads (Sidebotham and Zych 2016). In addition to commercial activities, there must have been cultural interaction among the diverse populations, both those dwelling in Berenike and also between the city's residents and itinerant visitors.

The port's ethnically diverse inhabitants ranged from those of lesser means to relatively wealthy as reflected in some of the finds (e.g., gold and pearl earring; undecorated gemstones and intaglios from signet rings; Proconnesian marble imported from northwestern Asia Minor and elsewhere used as floor/wall revetment; escargot shells from southern France/northern Italy; fancy tapestries used as wall hangings/furniture or floor coverings; other semiprecious stones – including a sapphire; and beads, many made of semiprecious stones and gold foil). Dedicatory inscriptions made by both men women residing in Berenike also indicate a portion of the population that was relatively wealthy. One inscription of the early second century CE mentions an aromatics warehouse in Berenike indicating that merchandise passed through the emporium enroute from markets in the Red Sea-Indian Ocean littorals to destinations in Egypt and the wider Mediterranean world (Ast and Bagnall 2015). Excavation of substantial amounts of black peppercorns, found both individually and in a large Indian-made jar containing 7.55 kg of this spice, and other imported commodities indicates that some exotic products were also consumed in Berenike itself.

Aside from a number of religious cult centers and some quays, wharfs, and piers, no other types of public buildings (e.g., baths, theaters, stadia, circuses, etc.) or monuments, except for a position of a *tetrapylon*/*tetrakionion* (viz., triumphal arches, dedicatory columns, etc.) have thus far been identified in the excavations. In addition, while most areas of the city have undergone at least some excavation, the majority of the southern side of the site has not.

Some industrial activities took place at Berenike: brick manufacture, production of lead, copper alloy, and iron nails, tacks, and fittings (for ship maintenance and repair, furniture making,

and likely some architectural applications); recycling of glass; making items from mica, beryl, sard, obsidian, selenite and turtle and mother-of-pearl shell; manufacture of cordage; basketry and matting; wood, leather, and animal horn working; and small-scale sculptural production in both Ptolemaic and Roman times. More *ad hoc* was the frequent patching, repair, and recycling of clothing and other objects made from textiles.

Scholars have debated extensively the nature of the commerce passing through Berenike and the trade between the ancient Mediterranean basin on the one hand and the "East"/northwestern Indian Ocean littoral (southern Arabia, East Africa, South Asia, to a much lesser extent the Persian Gulf) on the other. The long-held view that this was mainly a "luxury" trade for the elite must be reconsidered/modified in light of all the evidence (literary and archaeological) associated with Berenike and other contemporary Red Sea and Indian Ocean/Persian Gulf emporia. Reexamination of literary sources dealing with this commerce also suggests that this trade was not primarily one dealing in luxuries, but included both "necessities" and also more "exotic" items. The term "luxury" must be used with great caution as it would have depended on the socio-economic status of those using the items and in what context such items were consumed; often the term "luxury" reflects modern cultural bias rather than ancient sensibilities (Sidebotham 2011).

Some of the more noteworthy/unusual imports found in excavations at Berenike, mainly from the Roman era, were black peppercorns, coconut, rice, bamboo, jobs' tears (grass seeds from northeastern India), rosary beads (*Abrus precatorius* L seeds – rosary peas – from India), mung beans, *Boswellia* (genus of frankincense), seeds of the baobab tree, mastic, camphora, perhaps sandalwood, teakwood (from south India), and cedar wood (likely from Lebanon) (Cappers 2006; Zieliński 2011). The teak and cedar, for the most part, appear to have been the remains of dismantled ships recycled into the walls or ceilings of buildings or as shelving. There was a millennia-long Egyptian tradition for such reuse of ship timbers. Other imports included Indian textiles; resin from the Syrian fir tree (*Abies cilicica*) used in mummification and as an antiseptic and diuretic, sapphires (from south India/Sri Lanka); pearls (including five on a gold-wire earring); lapis lazuli; beads made of glass and semi-precious stones (many from South Asia, one from Java, some perhaps from Vietnam/Thailand); banded agate cameo blanks (from northwestern India); travertine (from southern Arabia) balsam; Indian (both fine wares and cooking/coarse wares), south Arabian and Axumite pottery; as well as some sherds of Persian Gulf and Nabataean provenance. Some sherds remain unidentifiable and may derive from the Indian Ocean coast of Africa. No extant literary evidence mentions some of these, while others were likely not trade items (pottery and beads) but ancillaries to commerce (containers for commodities) or were personal baggage of residents and visitors. Most pottery from Berenike is amphorae deriving from throughout the Mediterranean basin, Egypt, and the Middle East.

Conclusion

Excavations at Berenike and elsewhere in the Mediterranean, Red Sea, and Indian Ocean basins (including the Persian Gulf) over the past 30–35 years have documented the existence of "intercontinental" contacts (diplomatic and commercial and exchange of ideas and technologies) in Hellenistic times among Europe, Africa, and Asia. The scale of these connections was commercially greater in volume, involving a wider array of items (goods ranging from "luxury" to prosaic) and more extensive geographically in the Roman era and certainly more substantial overall in Roman times than previously believed. There is more evidence of diplomatic contacts and other exchanges in the early Roman period than in previous times. After a dramatic decrease in the Middle Roman period, vibrant contacts resumed in the late Roman (mid-fourth into the fifth century CE) era. Cultural exchanges (including philosophies and technologies) are more difficult to identify and measure, but most certainly occurred (Sidebotham 2011).

Concomitant to fieldwork at Berenike, the project has also conducted wide-ranging surveys and excavations in the environs and farther afield in the Eastern Desert, between the Red Sea coast and the Nile. This research provides a wider context in which to understand better Berenike's interactions with and importance to local and regional settlements as well as with the broader network within Egypt, the Mediterranean basin, and the Red Sea-Indian Ocean regions. The chronological range of sites spans from Neolithic (a cattle cemetery) to late Roman; the project also documented an RAF airfield from WWII. Types of sites documented by our regional fieldwork between the Nile and the Red Sea include roads, individual graves, *necropoleis* (animal and human), mines, quarries, fortified and unfortified road stations, route-marking cairns and *skopeloi*, and putative Christian *laura* communities (Sidebotham et al. 2008; Sidebotham 2011).

The American-Polish project will continue excavations at Berenike and survey-excavation in the desert hinterland for the foreseeable future.

Berlin Wall

Axel Klausmeier[1] and Leo Schmidt[2]
[1]Berlin Wall Memorial, Berlin, Germany
[2]Department of Architectural Conservation, Brandenburg University of Technology Cottbus (BTU), Cottbus, Germany

B

Introduction

In a surprise action during the night of August 12/13, 1961, the Communist government of East Germany (the German Democratic Republic or GDR) erected barbed-wire barriers to stop all traffic between East and West Berlin (Hertle 2011). These linked up with a system of barriers already in existence along the border between West Berlin and the GDR, effectively isolating West Berlin and controlling all access to it. The closed border quickly grew into a fortification system that became universally known as the Berlin Wall.

Since 1945, Berlin as the capital of Germany had been under Four-Power administration, internally divided into the Soviet sector (East Berlin) and the American, British, and French sectors (West Berlin). While the inner German border between the GDR in the east and the Federal Republic of Germany in the west (both founded in 1949) had been effectively sealed since 1952 as part of the Iron Curtain, communication and traffic between the western and eastern sectors of Berlin had remained practically unhindered, with many East Berliners crossing daily into West Berlin to work or to study and West Berliners buying cheap goods in East Berlin, thus adding to the pressures on East German economy. Even more problematic was the fact that Berlin remained, all through the 1950s, the one loophole in the Iron Curtain: East Germans could travel to East Berlin, the capital of the GDR: once in East Berlin, they could cross to West Berlin, be registered as fugitives from the GDR, receive West German citizenship and move out to West Germany via the official transit routes, particularly the air corridors. Until 1961, not less than 2.7 million East Germans

had left in this way – a dramatic loss for a country of roughly 17 million inhabitants (Wilke 2011).

The East German decision to close the border in Berlin depended on Soviet approval which was finally granted in the summer of 1961 (Harrison 2005). Part of the power play between the Soviet leader Nikita Khrushchev and US President John F. Kennedy, the closing of the border, and the propagandistically effective move of erecting a wall in the center of Berlin were not initially meant to be permanent, but to intimidate the West into agreeing to proposals of turning West Berlin into a "Free City" evacuated by the Western powers and dominated by the East. When it became clear that this strategy had failed, the GDR was faced with the task of turning the improvised barriers into a permanent "border regime" (Schmidt 2011a).

Key Issues/Current Debates/Future Directions/Examples

The Berlin Wall as a Structure

Within days, the barbed-wire barrier erected through Berlin was replaced by a wall – although it is worth noting that this first wall never extended beyond the city center. This first border wall was composed of breeze-block elements that were available in large numbers as they had been produced for the early prefabricated apartment houses of the GDR. This wall, usually about 2 m high, was topped by barbed wire strung along Y-shaped metal stakes (Fig. 1). Its perhaps deliberately brutal design and the fact that it was very unstable support the interpretation that this wall was largely built for propaganda purposes: It is known that the East German military favored the barbed-wire fencing that surrounded most of West Berlin and that it was Party Chief Ulbricht who insisted on a wall, presumably because it was more impressive visually.

During the following months, this initial structure was fortified and augmented in a number of ways, and in many places, the wall was raised by adding of extra courses. As a reaction to several successful escapes by fugitives breaching the wall with heavy vehicles, the breeze-block wall was sometimes replaced by barriers made of massive concrete slabs. Equally solid concrete elements were also employed in other locations, notably in Bernauer Strasse after the demolition of houses which stood directly on the border. Although involving only a limited modification of the earlier breeze-block structure, this concrete barrier has been termed the "second generation" Wall.

When it gradually became clear that the West was not going to give in to the Communists' demands and that the closed border in Berlin would become a permanent feature, the GDR

Berlin Wall, Fig. 1 Section of the Berlin Wall built in 1961 (Michael-Reiner Ernst)

began to devise a border system. In mid-1962, a border zone was institutionalized. Many buildings were demolished to make space for a death strip of varying depths – mostly about 50 m. A patrol road and a light strip parallel to the border were laid out, rough observation towers built of masonry or as wooden structures were erected, and the rear of the border strip, facing east, was secured by fences and a restricted area (Feversham and Schmidt 1999).

From the mid-1960s onward, all these border structures were superseded by a system of new border elements, consisting of a border wall constructed from concrete slabs set between concrete posts and topped by a sewage pipe (rendering it impossible for fugitives to get a grip on the top of the wall), a series of specially designed watchtowers featuring polygonal observation cabins on top of slender cylindrical concrete shafts, various anti-vehicle ditches and other obstacles such as "area barriers" consisting of metal grids with large steel spikes to impale fugitives trying to jump into the death strip from its eastern wall. Guard dogs in specially constructed runs also were an important feature, but – unlike the inner German border – no mines were ever used along the Berlin Wall.

Whilst this "third generation" Wall constituted a definite improvement over the improvised first version both in visual and structural terms, it proved to have so many defects and weaknesses that it was superseded, from the mid-1970s onward, by a "fourth generation," dubbed Grenzmauer 75 by its builders ("Border Wall 75"). This format was the result of an extensive research and trial program. Test walls were assembled from various prefabricated concrete elements – originally developed for agricultural purposes – and were exposed to simulated attacks. As a result of these tests, the L-shaped element UL12.41–1.2-m wide and 3.6-m high – was deemed most suitable for the border purposes (Fig. 2).

The "Border Wall 75" needed no foundations and was far stronger than its predecessor. Furthermore, it presented a smooth face toward West Berlin: an aspect of some significance to the GDR rulers who, from the early1970s onwards, became increasingly preoccupied with the image of their state toward the international public – an image tainted by the all-too obvious brutality of the border fortifications (Schmidt 2011a). The seamless and smooth western face of the "Border Wall 75" was quickly perceived as a limitless public canvas that seemed to invite the application of graffiti (Gründer 2007).

It should be noted that the structures of the border strip visible in Berlin – such as the border wall and the watchtowers – only constituted a part of all the elements that constituted the border system as this also comprised the extensive infrastructure required to control the border, such as the barracks for the border guards (roughly 10,000 soldiers) who patrolled the border with orders to shoot "border perpetrators" on sight rather than let them escape (Maurer 2011). The barracks of the five border regiments of Border Command Centre were arranged at different locations around West Berlin (Klausmeier 2009).

The Fall and Rise of the Wall

The story of the bloodless revolution that led to the sudden fall of the wall on November 9, 1989, has often been told (Henke 2009). In spite of warning voices, there was a broad consensus in favor of clearing away the hated border surrounding West Berlin as thoroughly as possible. Official demolition, carried out mostly by GDR Border Guards, began on June 13, 1990, in Bernauer Strasse, and was largely completed by the October 3, 1990, the day of German reunification. Thanks to efforts initiated by GDR Institute for Heritage Conservation as early as December 1989 and continued by the Berlin State Conservation Authority, a total of seven sections of the Wall and other border installations were listed and preserved as Historic Monuments by 1992. By 2011, this number had risen to 27, following intensive field research in and around Berlin (from Baker 1993 and Klausmeier and Schmidt 2004 to Cramer 2011; Berlin Wall GIS n.d.). While Berliners and their politicians had, all through the 1990s, mostly tried to forget the time of the division and to ignore the remnants and scars of the Wall in their city, the 2000s saw the rise of a new awareness of the Wall's significance, culminating in the

Berlin Wall, Fig. 2 Construction principles of 'Border Wall 75' (BTU)

celebrations of the 20th anniversary of the fall of the Wall. The Stiftung Berliner Mauer (Berlin Wall Foundation) funded in 2008 jointly by the Federal Republic of Germany and the Land of Berlin and its Landscape of Memory and Documentation Centre in Bernauer Strasse, both grown out of a private initiative in the 1990s, are a result of this new policy (Stiftung Berliner Mauer n.d.).

Perception and Cultural Significance

From the very start, public perception of the Berlin Wall was clouded and distorted by propaganda efforts. For example, even today, most people worldwide, when they think of the Berlin Wall, only ever imagine its western aspect. This is due to the fact that the GDR, whose name for the Wall was the "Anti-Fascist Protection Rampart," was interested in sustaining the fiction that the Wall was facing west – to repel the GDR's external enemies – rather than admitting that it was in fact facing east and had the primary purpose to prevent East Germans from leaving their own country. This fiction was upheld by rigorous control of any visual representation of the border's eastern aspect (hidden deeply within a restricted area) and aided by an attitude of the West of accepting the Border Wall they could see and touch as the only important element of the complex border fortifications.

By contrast, the eastern-facing wall – misleadingly called the "hinterland security wall" although it was, in functional terms, the main facade of the border installation – was never pictured or published in East or West. Therefore, the view of the border from the east must today be reconstructed as a computer visualization (Fig. 3). Perhaps ironically, the fact that the Berlin Wall was largely identified with the border wall and the watchtowers led to the effect that these elements were demolished with particular thoroughness whereas considerably more survived of the "hinterland wall" and other largely unnoticed border elements. Archaeological field research was able to identify previously unknown but revealing elements such as the "perimeter defenses": concrete walls, fences, and various obstacles (such as the

Berlin Wall, Fig. 3 Computer visualization of the border seen from the east (BTU)

heavy square concrete tubs known as "flower bowl barricades"); there were also metal grids barring windows close to the border strip, various spiky obstacles to prevent people from scaling fences and walls as well as additional light installations illuminating any possible hiding places in the vicinity of the hinterland Wall.

The color markings for Vordere Postenbegrenzung ('patrol limit') may be seen as a particularly graphic element of the border system revealed by archaeological field research and interpreted through oral history (Klausmeier and Schmidt 2004: 26). These markings, usually displayed on the lamp-post along the western side of the patrol road (Fig. 4), signified the line which ordinary border guards were not allowed to cross: If they did, they would themselves be regarded and treated as border violators. In fact, many Border Guards did attempt to flee, some of them either killing comrades or losing their own lives in the attempt (Hertle and Nooke 2011).

The exaggerated, even exclusive importance of the border wall in public perception is reflected in the curious phenomenon of the cult of Wall fragments. These are taken invariably from the Border Wall, and more specifically from its graffiti'd western face: No Wall fragment is deemed authentic unless it shows the colorful traces of paint layers. Immediately after the fall of the Wall in November 1989, "wallpeckers" began to hack fragments from the Wall; millions of these fragments were taken away by tourists and sold all over the world – like splinters from the True

Berlin Wall, Fig. 4 'Patrol limit', color marking on lamp-posts along the patrol road (BTU)

Cross, proof of our deliverance from the Cold War. The cult of Wall fragments is the result of a radical change of identity experienced by the Wall on November 9, 1990: From a symbol of oppression and death it had, by its unheralded fall, suddenly become an icon of liberation and hope. But not only small fragments of the Wall found their way to countless places around the globe: At least 120 Berlin Wall monuments, mostly made of full-size elements of the Border Wall, exist outside Germany, most of them in public, often very prominent spaces, but also within museums and public buildings – a unique case of a building or monument dispersed in authentic elements over all continents and recontextualized in many different forms (Kaminsky 2009; Schmidt 2011b).

The Berlin Wall has been a symbol and icon for many things (Kuhrmann et al. 2011) although the joyful memory of its fall overlays, for most people and particularly non-Germans, the memory of oppression and death. It is often used in comparison with other painful borders in the world although it should be pointed out that, unlike most other walls and fortified borders throughout history, the Berlin Wall was built to keep people in, not out.

Bettinger, Robert L.

Loukas Barton
Department of Anthropology, University of Pittsburgh, Pittsburgh, PA, USA

Basic Biographical Information

Robert "Bob" Bettinger (known simply as "Dr. Bob" to students of any age or degree) was born in Berkeley in 1949 and raised in the boom years of postwar California. Regular family expeditions from the Bay Area north to Fortuna (along the Eel River, in the redwood timber country of

northern California) induced lifelong interests in archaeology and ethnography. Indeed, it was the splendor and mystery of Native California that drew him to the prospects of anthropology in the first place, and to this day his research in archaeology is notable for its attention to ethnographic detail and insight.

As a college student at the University of California, Riverside, he was introduced to the challenges of archaeological fieldwork and to faculty commitments to economic anthropology, ecology, and analytical parsimony. Graduating Phi Beta Kappa in 1970, he continued his education at Riverside, completing a Ph.D. in 1975 under the guidance of Sylvia Broadbent, Erv Taylor, James O'Connell, and Martin Orans. During this time, O'Connell sent him to the Reese River Valley of Nevada to work with David Hurst Thomas on a pioneering effort to test hypotheses built from ethnographic records with systematic archaeological survey, sampling, and quantitative analysis. Bettinger's own dissertation (Bettinger 1975) expanded Thomas's Reese River program to the Owens Valley of California where better archaeological and ethnographic data helped to refine the analysis and interpretation of spatial patterns in hunter-gatherer activity.

By 1974 he was on faculty at New York University, where he made tenure in 1980. During the years at NYU, Bettinger and Thomas (also in New York, at the American Museum of Natural History) made the cross-country trek with their families to work in the Great Basin on a variety of collaborations and independent projects including excavations at Gatecliff Rockshelter, and systematic surveys in Monitor Valley, Nevada and Owens Valley, California. In addition to the volumes of first-rate research that came of it, the Great Basin archaeology of the 1960s and 1970s earned a separate reputation: a generation of archaeologists trained in western North America was raised on the preposterous exploits of these desert expeditions; subsequent generations were raised on the equally preposterous mythology of them.

A move to an untenured position at the University of California, Davis in 1980 brought him closer to home, closer to work, and on to a new research program in the White Mountains of eastern California. Some of the most enduring legacies of this period were the discovery of the highest elevation villages in North America and the behavioral logic explaining their existence (Bettinger 1991a). Tenure came quickly (by 1982) and this he attributes largely to the impact of a theoretical collaboration with the late Martin Baumhoff that explained the spread of the Numa, and the Uto-Aztecan language family, across the desert West (Bettinger and Baumhoff 1982).

In 1989, Bettinger and Great Basin veterans Robert Elston and David Madsen traveled to the interior of China on an invitation to apply the method and theory of Americanist archaeology to the Alashan Desert of Inner Mongolia (Bettinger et al. 1994). This international collaboration continues today and has expanded into neighboring Chinese provinces of Ningxia and Gansu, while remaining focused on late Pleistocene and early Holocene adaptive strategies and the origins of agriculture (Bettinger et al. 2010).

Major Accomplishments

Coursing through these regional, temporal, and topical foci is a career-long effort to refine and improve the theoretical foundations of hunter-gatherer archaeology. At the root of this effort is old-fashioned cultural ecology: Julian Steward's ethnography and interpretation of aboriginal life in the Great Basin permeate Bettinger's writing, from his dissertation on "man-land relationships" to some of his most recent work on the origins of private property. However, the early 1970s were awash in novel, elegant approaches to the biology of social organisms, and Bettinger (along with many other scholars) was unsatisfied with Steward's understanding of change through time. From this dissatisfaction emerged a new paradigm in human evolutionary ecology, and Bob Bettinger has been part of it ever since. Both his explanation for the Numic Spread, and the papers that preceded it were pioneering efforts to combine the economic logic of evolution in rational actors with the time-space dynamics of a multi-peaked

adaptive landscape. His ground-breaking, green-covered handbook on the evolutionary ecology of hunter-gatherers (Bettinger 1991b) continues to guide students through the simplifying logic of foraging theory and economic modeling. A more recent manual of step-by-step instructions, exercises, and practical applications (Bettinger 2009) makes the foraging models easier to learn. Critics of rational actor economic models often argue that their simplicity is unrealistic and that humans (indeed, any organisms) are too complex and too unprogrammed to follow such reductionist logic. Proponents of evolutionary ecology are of course aware of this complexity but prefer to approach the evolutionary consequences of it conservatively. They might instead begin with the insights of the basic evolutionary framework, expanding piecemeal to explore more complicating features of human behavior affecting inheritance, adoption, variation, and survival. For example, if the very mechanics of human learning and information-transfer affect the evolutionary process, how might these patterns of learning and evolution be detected in the archaeological record? Bettinger and colleague Jelmer Eerkens (1999) provide us with one of the earliest and to date one of the best applications of this cultural transmission theory in archaeology, by evaluating Great Basin projectile points and the spread of bow-and-arrow technology.

Underpinning this career-long dedication to the patterns of human cultural evolution is a very general philosophy for archaeology: "good science can handle meager data with excellent theory, but without really good theory you better have damn-good data." To students and colleagues from California to China and Argentina to Siberia, this oft repeated dictum is known as "Robert's Rule."

In 2007 Bettinger received the annual Award for Excellence in Archaeological Analysis from the Society for American Archaeology.

Bhattacharya, Dibyendu Kanti

Manoj Kumar Singh
Department of Anthropology, University of Delhi, Delhi, India

Basic Biographical Information

Dibyendu Kanti Bhattacharya (Fig. 1) was born on June 28, 1939. He was the son of Mr. Jitendra Mohan Bhattacharya and his wife Manorama. He has five brothers and two sisters. When he was 5 years of age, he was not a healthy person, and he once heard his parents discussing that he could not survive for long and he should be allowed to do whatever he wished while he was alive. This whisper affected him strongly, and he would never give in to his weakness. Even today, in the throes of severe asthma during certain parts of the year, he has never stinted from his teaching, research, and fieldwork. In May 1958, he ran away from home and joined the Bhoodan movement under Vinoba Bhave because he wished sincerely to work for the people. He remained in there for 6 months travelling all over Sholapur district in Maharashtra. Due to this, he had trouble

Bhattacharya, Dibyendu Kanti, Fig. 1 Photo of Bhattacharya, Dibyendu Kanti

in getting admitted to the University of Delhi in the M.Sc. course. He completed his M.Sc. in 1960, securing a first division, and was awarded a Ph.D. in 1965, his thesis titled *A Study of ABO, RH-HR, MN Blood Groups Among the Anglo-Indians of India With a Note on Some Other Morphological Traits* from the Department of Anthropology, University of Delhi.

He was the lecturer at the Department of Anthropology, Lucknow University, in 1965–1966. In 1966, he joined as a lecturer at the Department of Anthropology in the University of Delhi. In 1969, he was married to Pratibha, a grandniece of Veer Savarkar. In December 1971, he went to Germany and stayed there for 3 years. He also went to Great Britain, Denmark, Norway, Sweden, Austria, and Switzerland.

In August 1974, his daughter was born. He became a reader in 1985 and in 1991 became a Professor in the Department of Anthropology, University of Delhi. Between 1993 and 1996, he was the Head of the Department, Department of Anthropology, and University of Delhi. He was the visiting Professor at the Department of Anthropology, Lucknow University (in April 1997), at the Karnataka University, Dharwad (September, 2002) S.V. University, Tirupati, in October 2002.

He was the member of the UGC's visiting team to evaluate the tenth plan at Vidyasagar University, Midnapur, in November 2002. He is an

associate of the Journal Current Anthropology, published by the Wenner-Gren Foundation from the USA. He is a member of the Anthropological Society of Nippon, Japan, and a life member of the Indian Science Congress Association, Kolkata; the Indian Anthropological Association, Delhi (of which he was one of the founders); the Ethnographic and Folk Culture Society, Lucknow; the Indian Society for Prehistory and Quaternary Studies, Pune; the Indian Archaeological Society, New Delhi; and the S.C. Roy Institute of Anthropological Studies, Ranchi.

Bhattacharya speaks English, Hindi, Bengali, German, and Marathi fluently. His major geological areas of interest include in other areas of Madhya Pradesh, the Chotanagpur region, and West Bengal, though he has also worked in other areas including Rajasthan, Orissa, Gujarat, and Maharashtra.

Major Accomplishments

Professor Bhattacharya has spanned a career in Indian Archaeology for almost 40 years. In his career, he has been bestowed with many honors. During his time at the Department of Anthropology in the Lucknow University, he was assigned an almirah in which he found several bones. On asking he was informed that these bones were from a place called Roopkund in the Uttaranchal Himalayan region. After reading up on the mysteries of this region, he had decided to work on this and other materials found from the region. This was awarded recently, when he and others worked on this material in 2001 for the National Geographic Program to give a summary on the findings of the Roopkund Mystery.

In 1972 he had written the first of his textbooks on this subject. He was awarded a D.Litt. from Ranchi University in 1983, in which he worked on a major outline of European prehistory entitled Paleolithic Europe. This book was later published by the Humanities Press. When Prof. Bhattacharya came back to India, he had written a book on stone tool typology, realizing that such a work was unique and had not been systematized. In India, under the guidance of Prof. Bhattacharya, the first such typo-technologies of Stone Age tools were available. Till date, even in many foreign universities, such a typo-technology is not aught and is expected often to be worked out by the students on their own. As a result, his special interest ranged from Physical Anthropology, Palaeoanthropology, Prehistoric Archaeology, and Human Ecology.

He delivered the Panchanan Mitra lecture at the Asiatic Society, Kolkata, in 1993. He was granted the Dharni Dhar Memorial Plaque by the Department of Anthropology, Calcutta University, on March 13, 1997. He was unanimously selected the President of the Anthropology and Archaeology Section of the 86th Indian Science Congress held in Chennai in January 1999.

He also delivered the first D.N. Majumdar Memorial Lecture at Lucknow on March 2, 2003. He was also the coordinating author for the chapter on "Cultural Services" sponsored by the Millennium Ecosystem Assessment. As a result, he visited Indiana University, Bloomington and Indianapolis, USA (in January 2003); Frankfurt, Germany (in May 2003); and Czech Republic (in October 2003).

Bhimbetka Rockshelters

Manoj Kumar Singh
Department of Anthropology, University of Delhi, Delhi, India

Introduction

Bhimbetka is a hill containing over 200 caves and rockshelters located 45 km south of Bhopal, of Raisen district, near the Bhiyapura village of Madhya Pradesh, situated along the Bhopal-Hoshangabad highway, in the northern fringes of the ancient Vindhyachal range. The rock paintings were discovered by V. S. Wakankar, who surveyed the area in 1957. Since 1990, this complex of sites is protected and maintained by the Archaeological Survey of India and recognized as World Heritage by UNESCO. Other adjoining hills are equally rich in caves and rockshelters, and altogether there are over 1300 of them in an area of 10 km length from east to west. More than 500 of these sites contain paintings. Excavations in over a dozen shelters at Bhimbetka have revealed a continuous occupational history from Acheulian to Mesolithic times. The paintings are found on walls and ceilings of the shelters, usually on large even surfaces but sometimes also in small hollows or niches. The majority are within easy reach but some are situated at considerable heights and also at inconvenient places where standing support would be needed.

Key Issues/Current Debates/Future Directions/Examples

Content and Style of the Art

The majority of the paintings are in red or white colors but some are also in green. Based on the Raman spectra and the elemental analysis, mineral-based pigments such as calcite, gypsum, hematite, whewellite, and goethite could be identified to have been used for painting. The latter are most poorly preserved and are probably the oldest. Broadly the paintings can be divided into two cultural and chronological phases: (1) prehistoric and (2) historic. The prehistoric paintings are dominated by the depiction of wildlife, which includes various species of deer, antelopes, wild boar, elephant, rhinoceros, tiger, wild buffalo, wild cattle, fox, jackal, and fish. Birds are shown but are rare. The animals are shown individually as well as in groups and in standing, grazing, moving, and running positions. Some animal figures are marked by composite characters, like those of a boar and a bull, and probably represent mythical creatures. There are frequent hunting scenes with men hunting individually or in groups and using spears, bows and arrows, traps, and snares. The spears and arrows are tipped and barbed with what appear to be microliths. Other food-gathering activities shown include men and women fishing and climbing trees with baskets suspended on their backs to collect fruit, flowers, and honey. There are scenes of human life like group dances, drinking, pregnancy, care of the sick, and mourning. Two petroglyphs excavated in Auditorium Cave (Bhimbetka III-24) were covered by the uppermost part of a substantial Acheulian layer, which according to R. Bednarik must be the oldest rock

art in the world. This assertion remains controversial and has yet to see wide acceptance by rock art researchers in India and beyond. The later and historic paintings, which are often superimposed over earlier paintings, have limited repertoire of themes. They mostly depict royal processions and battle scenes with men riding caparisoned horses and elephants and fighting with metal tipped spears, bows and arrows, swords, and shields (Figs. 1, 2, and 3).

A brief description of seven periods of the rock art in Bhimbetka is as follows:

Bhimbetka Rockshelters, Fig. 1 Deer of Bhimbetka

Period I-(Upper Paleolithic) These are linear representing, in green and dark red, huge figures of animals, such as bison and boar beside sticklike human figures.

Period II-(Mesolithic) Smaller in size compared to the earlier period, the stylized figures using symbols in this group show linear decorations on the body containing animals, human figures, and hunting scenes giving a clear picture of the weapons they used like barbed spears, pointed sticks, bows, and arrows. The depiction of communal dances, birds, musical instruments, mother and child, pregnant women carrying dead animals, drinking, and burials appear to capture motion in different situations.

Period III-(Chalcolithic) Similar to the paintings on the pottery of the Chalcolithic, these drawings reveal that during the period, the cave dwellers of this area were in contact with the agricultural communities of the Malwa plains and exchanged goods with them moving towards more civilized societal colony.

Periods IV and V-(Early Historic) The figures of this group have a schematic and decorative style and are painted mainly in red, white, and green. The presentation of riders, depiction of religious symbols, tunic-like dresses, and the existence of scripts of different periods are significant

Bhimbetka Rockshelters, Fig. 2 Mail Hall of Bhimbetka

Bhimbetka Rockshelters, Fig. 3 Bull of Bhimbetka

departure from the earlier period. The religious beliefs are represented by figures of Yaksha, tree gods, and magical sky chariots.

Periods VI and VII-(Medieval) These paintings are formed out of geometric, linear, and more schematic, but they show degenerations and crudeness in their artistic style compared to the earlier stage may be due to mass production of routine themes. The colors used by the cave dwellers were prepared combining manganese, hematite (soft red stone), and wooden coal. Paintings on the concepts of Brahmanical gods like Ganesh and Nataraja are considered the contribution of this period.

There is considerable variety in the portrayal of animal figures of the earlier phase. The animal body is drawn only in outline, or it is wholly or partially filled with color or is decorated by geometric patterns like straight or wavy lines, dots, crisscrosses, and other more complex designs. The animal figures are characterized by naturalism, vitality, and vigor. The majority of these paintings are highly mature artistic creations and suggest a long evolutionary period behind them. In contrast, the paintings of the historic phase are stylized, repetitive, and devoid of realism. The latest among them depict animals in a highly distorted and conventionalized manner. It is obvious that the artists who drew them were no longer inspired by natural life around them but were only repeating traditionally accepted motifs.

Binford, Lewis R. (Hunter-Gatherer and Mid-Range Societies)

Robert L. Kelly
Department of Anthropology, University of Wyoming, Laramie, WY, USA

Basic Biographical Information

Lewis R. Binford (1931–2011) was born November 21, 1931 in Norfolk, Virginia.

He studied wildlife biology at Virginia Polytechnic Institute. But military service in Japan during the Korean War led him to an interest in other cultures, and, after the war, he studied anthropology and archaeology at the University of North Carolina. He attended graduate school at the University of Michigan, graduating in 1964 with a dissertation on the archaeology and ethnohistory of coastal Virginia.

Binford taught at the Universities of Chicago, California (Santa Barbara and Los Angeles), New Mexico, and Southern Methodist University. He published over 150 papers, books, reviews, and comments and received much recognition, including election to the National Academy of Sciences.

Major Accomplishments

Binford was the chief architect of the *new* or *processual* archaeology. In the 1950s, archaeologists focused on artifact classification, and they saw artifacts as reflections of mental templates, useful for tracking the migration of cultures or the diffusion of ideas. Through a series of papers, Binford (1962, 1964, 1965, 1967, 1968a) challenged archaeologists to do more, to fully participate in anthropology, and to rely on scientific methods. Revolutionary at the time, Binford's approach became *de rigueur* by the 1970s (see compendiums of his papers in Binford 1972, 1983b, 1989).

Binford took a materialist approach to prehistory, relying on Leslie White's concept of culture as *man's extrasomatic means of adaptation*. He focused on hunter-gatherer societies and helped pioneer ethnoarchaeology (with research among the Nunamiut and Australian Aborigines), as well as faunal analysis, sampling, spatial analysis, and the use of statistical methods. He introduced concepts that are now so common in archaeology that one forgets he invented them, e.g., residential and logistical mobility, foragers and collectors, curated and expedient tools, technological organization, and, most importantly, middle-range theory (e.g., 1978a, 1979, 1980).

Middle-range theory was aimed at making reliable inferences from archaeological remains. Binford argued that archaeologists relied on simple rules of thumb for interpretations (1977, 1981a, 1983a). Using the geological principle of uniformitarianism, he sought unambiguous links between human behavior or natural processes and their material traces. His work with the Nunamiut was pivotal here (1978b). Grounded in the food utility of different parts of animal anatomy, he used Nunamiut butchering practices to show how faunal assemblages differed depending on circumstances (e.g., fall hunts designed to store food vs. spring hunts for immediate consumption). The resulting patterns in Nunamiut faunal assemblages could then be used to interpret archaeological assemblages – not as analogues but as middle-range theory because the *causes* of the patterns were sought and explained in terms of the intrinsic elements of animal anatomy. As long as ancient and modern animal anatomy was the same, the patterns of different butchering goals should also remain the same.

Binford was not interested in an ethnographic reconstruction of the past. Instead, he argued that archaeology's power lay in its ability to see processes on a scale that ethnography could not – time spans of thousands of years and spatial

variation across continents. He used specific archaeological cases to understand processes of change and causes of diversity among hunter-gatherers. Consequently, he was never a prehistorian of a particular region. Nonetheless, he contributed seminal research to several important questions, including the meaning of variability in Mousterian stone tool assemblages, the origins of agriculture, and the role of hunting in human evolution.

French archaeologist François Bordes argued that variability in Mousterian stone tool assemblages reflected different mental templates and hence different *tribes* of Neanderthals. Binford (Binford and Binford 1966) argued that the assemblages reflected different functional uses of a cave as the settlement system shifted to adapt to changing circumstances (1982). Likewise, he argued that agriculture was not the inevitable product of the accumulation of knowledge but was instead an adaptation to high population density (1968b). In the 1980s, he used ethnoarchaeological and taphonomic research on faunal remains to argue that our earliest human ancestors were not hunters of large game, who foraged in much the same manner as modern hunter-gatherers, but were instead lowly scavengers of the animal carcasses left behind by large carnivores (1981b, 1983a). His studies of variability in lower Paleolithic stone tool assemblages led him to argue that those early makers of stone tools were not simply shorter, hairier versions of ourselves but hominins who were not human in the way we know humans.

His magnus opus, *Constructing Frames of Reference* (2001), was the result of a lifelong effort to compile ethnographic data on hunter-gatherer societies and environmental data in order to model prehistoric life based on paleoclimatic reconstructions.

Binford was a thinker who thrived on challenging orthodoxy and authority. He was a prolific writer, a mesmerizing speaker, an excellent teacher, and a theoretician who understood dirt archaeology. While many of his specific interpretations may not stand the test of time, he helped shape archaeology into the field it is today.

Binford, Lewis R. (Theory)

Lu Ann Wandsnider
University of Nebraska, Lincoln, NE, USA

Basic Biographical Information

Lewis Roberts Binford was born on November 21, 1931, to J. Lewis Binford, from rural Appalachia, and Eoline Roberts Binford, of the genteel Tidewater area of Virginia. When he died on 11 April 2011, newspapers around the world noted his passing and memorialized his accomplishments. Binford was the quintessential southern gentleman, a charismatic lecturer, and an inspirational teacher, who, through force of personality, great intellect, and roll-up-your sleeves hard work, transformed the conduct of archaeology. He loved life and living, which for him was synonymous with learning and challenging. Everything he did during his time on the faculties of the University of Chicago (1961–1965), University of California–Santa Barbara (1965–1966), University of California–Los Angeles (1966–1968), University of New Mexico (1968–1991), and Southern Methodist University (1991–2003) was accomplished with infectious gusto, attracting both loyal admirers and some detractors, too.

Binford's formal education included undergraduate studies in wildlife management and wildlife biology at Virginia Polytechnic Institute, laying a foundation for his scientific ecological approach. From 1952 through 1954, he served in the US Army as an interpreter to anthropologists charged with the post-World War II transition in the western Pacific, which exposed him to new career possibilities. When he returned to school at the University of North Carolina, he shifted to anthropology, studying with Joffre Coe and completing a B.A. (1957). His M.A. (1958) and Ph.D. (1964) were completed at the University of Michigan, where he was influenced by Leslie White, champion of the scientific study of culture change, and where he challenged James Griffin, dean of eastern North American culture history.

Family and the school of hard knocks also shaped Binford. His father was an important influence, and, like others, Binford's family circumstances during the Great Depression and after were difficult; even as a boy he was working to help his family get by. There were no handouts for Binford and anything that came his way was through hard work, which continued throughout his life. His skills as a carpenter fed him during graduate school and served as a counterpoint for his writing; students in the 1970s and 1980s saw him transform his house in Corrales, New Mexico, by day and, by night, transform archaeology as he crafted *Nunamiut Ethnoarchaeology*, *Bones: Ancient Men and Modern Myth*, and other tracts. And, from an early age, Binford was keen observer of the human condition, noting the tensions between class and privilege (associated with his mother's family) and getting the job done so one could eat (seen in his father's family) (Sabloff 1998). The challenges to voices of authority for their insistence on privilege over substance, unmistakable in Binford's early career, perhaps emanated from these formative experiences.

Major Accomplishments

In 1962, Lewis Binford (1962a) published "Archaeology as Anthropology" in the flagship journal for archaeology in the United States,

American Antiquity. Adapting Leslie White's (1959) definition of culture as a system, with material culture viewed as simultaneously operating in technomic, socio-technic, and ideo-technic cultural subsystems, Binford argued that ALL aspects of culture were archaeologically accessible, fundamentally transforming archaeological discourse (Watson 1995).

"The most competitive people are the ones who do the most similar things" noted Binford (Sabloff 1998: 8), referring to the late 1950s debates between Julian Steward and Leslie White. This also described his own working style. For Binford, insights emerged not from the discovery of facts in the field but from thinking about and through these encounters with the real world. To this end, public debate with other competent thinking debaters – in print or, better still, in person – was a vital learning tool. Thus, he challenged Robert Braidwood, preeminent Near Eastern scholar, on the nature of the origins of agriculture there (Binford 1968); sparred with François Bordes, master of the French Middle Paleolithic, over the interpretation of Mousterian assemblages (referred to as the form vs. function debate, authored with his third wife, Sally Binford; Binford and Binford 1966); and jousted with Glynn Isaac, the reigning expert on early hominid behavior in East Africa, over interpretation of east African materials (Binford 1987). His 2001 book, *Constructing Frames of Reference* (for which he acknowledges the substantial assistance of his fifth wife, Nancy Medaris Stone) represents in part his response to the critique of Processual Archaeology offered by Ian Hodder and others beginning in the 1980s. Binford rarely passed up a good argument, and, after putting away the boxing gloves, he often supped and celebrated with his opponent.

Binford's accomplishments and contributions are best described as fundamental and groundbreaking. He is often acknowledged for launching, with collaborators at the University of Chicago, the New Archaeology (later, Processual Archaeology), a self-styled movement within archaeology that asserted that archaeology could contribute fully to the project of anthropology and need not be the hapless sibling of cultural anthropology, crippled by an impoverished data set. The 1968 edited volume, *New Perspectives in Archaeology* (coedited with Sally Binford), presented early challenging case studies. As part of this large and continuing effort to refashion archaeology, Binford laid several metaphysical, paradigmatic, conceptual, and methodological foundations that the discipline continues to build upon today.

Metaphysically, Binford (and others, notably, David Clarke and Michael Schiffer) moved the discipline from one based in simple synchronic reconstruction, consistent with functional goals, to one situated in a taphonomic or formational metaphysic, i.e., recognizing and exploiting the many agents that interact to form archaeological deposits. His work with Middle Paleolithic and hominid deposits emphasized that others besides protohumans accumulate and arrange bones in caves and that fire was not a gift uniquely given to humans (*Bone: Ancient Men and Modern Myths*, 1981). This less often acknowledged metaphysical transformation has greatly expanded archaeological interpretative possibilities.

From the inception of archaeology, debate has ensued over the nature of archaeological science. In the 1950s, archaeological science involved an eminent authority amassing observations on archaeological deposits and, from these, weaving a comprehensive interpretation based in common sense (sensu Dunnell 1982). Binford argued for a very different version of archaeological science. For him, science was solely about the evaluation of ideas, whatever their source, with experience. This meant that one had to identify what one securely knew (both archaeologically and in the contemporary world), identify the domains of ignorance, and then build bridges from knowledge to illuminate ignorance. *Constructing Frames of Reference* (Binford 2001) is an explicit statement and extended example of Binford's version of science. Here, in an effort he worked on throughout his career (see Binford 1980), Binford organized and presented two sets of information about hunter-gatherer-fishers between which he tacked to identify provocative patterns in need of further exploration. The first includes basic structural information on physical environments, along

with an energy-based model of how clever human predators deploying different organizational structures operate in those environments. The second includes a compendium of ethnographically documented hunter-gather-fishers and how in fact they are found to have behaved in different environments. Binford moves back and forth between these two domains, identifying patterned variation seen in foragers through time, proposing explanations for this variation, and, contra his earlier critics, recognizing the contingent role of prior organizational poses.

Buttressing his metaphysical and paradigmatic innovations, Binford's methodological innovations are many. Two stand out. The first are various tools for managing archaeological variation. Certainly, a budding appreciation for the important role of variation in phenomenon under scientific scrutiny is evident in the work of 1950s archaeologists (e.g., see the Ford-Spaulding debate). With his 1964 *American Antiquity* article, "A Consideration of Archaeological Research Design", Binford brought to archaeology the parlance of sampling, which has since been reified in practice in heritage archaeology. His 1966 paper with Sally Binford, "A Preliminary Analysis of Functional Variability in the Mousterian of Levallois Facies", was one of the early applications of multivariate analysis in archaeology, identifying dimensions of variation in Near Eastern Middle Paleolithic assemblages. With the desktop computing revolution in the 1980s, such applications have become more routine and sophisticated.

In addition, Binford enlightened a critical component of the archaeological enterprise, which he referred to early on as middle-range theory (1977; see also formation theory, middle-range research, midrange theory, source-side knowledge, bodies of reference knowledge). That is, recognizing that archaeological materials cannot speak for themselves, Binford emphasized that archaeologists must give archaeological materials a language with which to speak. This language comes from the contemporary world and requires development by archaeologists for archaeological interpretation. Binford's 1967 *American Antiquity* article, "Smudge Pits and Hide Smoking: The Use of Analogy in Archaeological Reasoning", was his first article expressly concerned with how archaeologists assign meaning to archaeological materials. Thinking on this topic matured as Binford confronted Middle Paleolithic assemblage variation and its interpretation, recognizing that the functional interpretation he and Sally Binford had offered represented a "just so story" slightly more compelling than that offered by Bordes. As illustrated in his *Nunamiut Ethnoarchaeology* (1978b), middle-range work proceeded on two fronts. Binford turned to work with contemporary native hunters in the Brooks Range of Alaska not as analog for the Middle Paleolithic ice age but to understand some of the many conditions under which variation was introduced into faunal assemblages. In addition, he undertook experimental studies to map the economic dimensions of carcasses, against which assemblage variation could be assessed. Ethnoarchaeological, experimental, and other taphonomic studies established what Binford referred to as intellectual anchors to be used in interpreting archaeological patterning. Construction of similar intellectual anchors was attempted for spatial data (Binford 1978a) and chipped stone assemblages (Binford and O'Connell 1984).

Further maturation on this topic is clear in his *Constructing Frames of Reference*, in which he moved beyond "middle-range theory" as a simple Rosetta stone connecting pattern and process. In part, this is owed to his enduring interest in culture systems, how they are organized and how they change through time. Middle-range research, confined as it is to ethnographic scale phenomenon, could not illuminate the supra-generational phenomena that so interested Binford. *Constructing Frames of Reference* offers a research strategy for such phenomena.

Throughout his career, Binford was an innovator and a pioneer. His 1962 regression formula for dating pipestems is still widely cited in historical North American archaeology (Binford 1962a). And, while employed by the National Park Service on the Carlyle Dam project in southern Illinois, he collaborated in pioneering

systematic surface collection (Binford et al. 1970).

Over the last several decades, the contributions of Lewis Binford, the provocateur and the scientist, have been increasingly recognized. Binford received honorary degrees from the University of Southampton (1983), Pierre Mendez France University (1999), the University of Leiden (2000), and the University of Verona (2005). In 1986, he received the Huxley Medal from the Royal Anthropological Institute. He was elected a corresponding fellow of the British Academy in 1997 and elected to the US National Academy of Sciences in 2001. In 2008, he received the Lifetime Achievement Award from the Society for American Archaeology. An asteroid (213629 Binford = 2002 QK67) orbiting the Sun between Mars and Jupiter was named for him in 2010. His 1984 book *In Pursuit of the Past*, distilled by John Cherry and Robin Torrence from a series of lectures delivered in Europe in the early 1980s, has been reissued (2002) and translated into multiple languages.

Bioarchaeology in the Roman Empire

Kristina Killgrove
Department of Anthropology, University of West Florida, Pensacola, FL, USA

State of Knowledge and Current Debates

Much of a person's life history is written on his or her bones. Skeletal remains of past populations are palimpsests of information about the behaviors people engaged in during their lives. The bioarchaeological study of burials from around the Roman Empire is a relatively new undertaking but has proven to be an essential line of evidence for understanding the demographic makeup, health status, and dietary regimes of the heterogeneous peoples that comprised the imperial population. Bioarchaeologists are therefore leading the way in answering questions about the life experiences of all social classes in the Roman Empire. By integrating bioarchaeological studies with traditional analyses of material culture and texts and with innovative and interdisciplinary biochemical analyses, the diversity of the Romans in all areas of the Empire is becoming apparent.

State of Knowledge

Bioarchaeology is the study of skeletal remains from archaeological sites (Buikstra 1977; Larsen 2015; Martin et al. 2013). The term osteoarchaeology is also used, primarily in Europe, and through the years both terms have been broadly defined as including skeletal material from both humans and animals. Owing to the influence of New Archaeology, however, since the 1970s, bioarchaeology has conventionally dealt with the physical remains of humans from burials found in the archaeological record. In the USA, bioarchaeology is considered a subspecialty of biological anthropology, whereas in Europe the field is more closely allied with archaeology and anatomy.

An individual skeleton is the unit of analysis in bioarchaeology, but inferences about past behavior can only be reconstructed through a survey of the population and its sociocultural context. As such, bioarchaeology is an interdisciplinary field, incorporating techniques and theoretical approaches drawn largely from biology, chemistry, anatomy, demography, anthropology, and archaeology. When used as a way to study the people of the Roman Empire, bioarchaeology also draws from classical philology, historiography, epigraphy, architecture, and artifact studies in order to situate the skeletal population under consideration within a cultural milieu.

In one sense, the roots of classical bioarchaeology can be found in ancient authors. In the mid-fifth century BCE, Herodotus, reporting on the aftermath of a Persian War battle (*Histories* 3.12.2-3), noticed that the skulls of the Persians were brittle, whereas those of the Ethiopians were quite strong, and he attributed this difference to sun exposure by the Africans. While Herodotus was not correct in this correlation, his observation foreshadowed discussions in biological anthropology of the effects of the environment on the human skeleton.

The osteological study of burials has been a part of Roman archaeology since at least the nineteenth century. At this time, cursory analysis of skeletons with the objective of culling demographic histories was always subsumed by publication of grave goods in large site reports, sending biological material to languish in appendices. The biological sex of a skeleton was assigned based on associated artifacts as often as it was estimated by biological markers. In the early twentieth century, biological anthropology in the USA and Europe developed similarly, as researchers attempted to look at skeletons, especially the skull, for evidence of diffusionary traits. Coupled with such pseudoscientific tools as Retzius' cephalic index, biological anthropology in Italy, for example, became heavily invested in discovering the "true race" of the Italians and explaining the Mezzogiorno and American anthropology in finding a biological basis to support the practices of slavery, racism, and forced removal of Natives. Skeletal measurements, when twisted to fit preconceived notions of racial superiority, represented both a reliance on early empiricism and the rise of nationalist movements in Europe and America. This legacy of cranial indices and -cephalic

suffixes, unfortunately, is still seen today in some Mediterranean bioarchaeological publications, but the field has evolved immensely in the last decade.

Bioarchaeology in the English-speaking world arose as an independent field of research in the 1970s under the guidance of US anthropologist Jane Buikstra and other proponents of the science-focused New Archaeology. Researchers began to study skeletal collections housed around the world in order to answer research questions beyond chronology and typology of burials. In the 1980s, with the advent of post-processual archaeology, bioarchaeologists started asking how diet, behavior, and disease differed along the lines of status and gender. By the 1990s, bioarchaeology was coming into its own. Data recording practices and techniques were standardized in the USA (Buikstra and Ubelaker 1994), and European researchers similarly adopted their own standards (e.g., Brickley and McKinley 2004). At the end of the twentieth century, several international laboratories and research centers that deal with classical bioarchaeology had been established, such as the Wiener Laboratory at the American School of Classical Studies at Athens, the Servizio di Antropologia of the Soprintendenza Speciale per i Beni Archeologici di Roma, the Centre National de la Recherche Scientifique in France, and English Heritage in the UK.

In the twenty-first century, bioarchaeology increasingly employs chemical techniques such as isotope and DNA analyses to answer questions about population interaction, dietary differences, and the origin and spread of disease. There has also been a trend toward osteobiography or creating detailed, individualized life histories from skeletal remains, often accompanied by a forensics-based facial reconstruction. Classical bioarchaeology today is balancing scientific and humanistic approaches in order to understand life in antiquity.

Current Debates

Although classical archaeology was founded on an historical tradition in which material remains were mainly used to illustrate the vast body of Latin literature, today's Roman bioarchaeologists ask their own questions about what life was like in ancient times, in part to provide a history to those segments of society that did not merit inclusion in elite writing. Key areas of Roman bioarchaeology research in the past decade have focused on questions about diet, migration, and disease in the Empire. The majority of this research has been done on skeletal assemblages from Italy and from Britain and has been published in the traditional venue of peer-reviewed anthropology journals. As more bioarchaeologists have begun focusing on the periphery of the Empire, however, new research can be found in a variety of languages and publication venues. There is additionally a growing movement toward synthetic treatment of bioarchaeological data from the classical world that is reaching an audience made up of anthropologists, classicists, historians, and the general public.

1. *Diet: What Were People Eating Around the Empire?*

The Imperial Roman diet, particularly for the lower classes, has been reconstructed primarily through the agricultural writings of authors such as Cato, Varro, and Columella. People in all parts of the Empire subsisted on cereals, fruits, and vegetables generally in the form of bread, olive oil, and wine. There is little evidence in historical records, however, of the diversity that existed in the Roman diet, and there has been disagreement about the role of seafood and the consumption of millet. Bioarchaeologists have weighed in with chemical analyses of skeletal tissue in an effort to demonstrate that different imperial populations used different alimentary resources.

Carbon and nitrogen isotope analyses from bone collagen yield a general picture of a person's diet in the years leading up to death. Because carbon enters the food chain through photosynthesis, a human's carbon isotope ratio is largely affected by the kind of plants he or she ate. Additionally, there are two major photosynthetic pathways, which mean that carbon isotopes can distinguish a diet reliant on temperate grasses such as wheat and barley from a diet reliant on

tropical grasses such as millet and sorghum. Nitrogen in the human diet is obtained primarily through consumption of other organisms, so understanding nitrogen isotopes means understanding an organism's position in the food chain. The values of nitrogen isotopes therefore range from very low, indicating a diet composed of legumes, to very high, indicating a diet composed primarily of aquatic resources.

Isotope research on skeletons from Imperial Italy has shown great differences in diet. In the shadow of the city walls of Rome, people were eating more millet and less seafood than were people from Portus Romae (Prowse et al. 2004; Killgrove and Tykot 2013, 2017). Skeletons from the early Christian necropolis of San Callixtus in the Roman suburbs further revealed an ascetic diet for this religious group, with consumption of freshwater fish from the Tiber River (Rutgers et al. 2009). Correlation between frequency of external auricular exostosis, an ear pathology related to cold water immersion, and nitrogen isotope values for people from Portus and Velia, a site on the Tyrrhenian coast, further demonstrates that the population of Imperial Italy was indeed consuming both freshwater and saltwater resources (Craig et al. 2009; Crowe et al. 2010). Differences in diet at Portus have also been found to reflect age, with children eating more terrestrial food and older adults consuming more olive oil and wine (Prowse et al. 2005), and there is evidence that foreigners at Rome changed their diet after immigrating and consumed less millet (Killgrove and Montgomery 2016). Further south, dietary isotope research on Herculaneum (Craig et al. 2013; Martyn et al. 2017) has produced data on varied diets that line up with archaeological and paleobotanical studies from the site.

Outside of Italy, palaeodiets varied within populations and through time in Roman Britain (Müldner 2013); nevertheless, isotope studies on several skeletal series have revealed that Romano-British people ate a largely terrestrial diet composed of plants, meat from herbivores, and a small amount of marine or freshwater fish. Other studies have focused on sites along the Roman *limes*, such as at Leptiminus in Tunisia (Keenleyside et al. 2009), the Dalmatian Coast of Croatia (Lightfoot et al. 2012), Denmark (Jørkov et al. 2010), and Spain (López-Costas and Müldner 2016), and similarly reveal a wide range of exploited foodstuffs. Whereas people in North Africa were eating some marine resources and adult diet was different from kids' diets, there was virtually no consumption of fish in Denmark, and everyone was eating similar food. Croatia and Spain provide evidence that being part of the Empire affected people's daily diets; while the Roman period meant more marine resources consumed in Croatia, in Spain the transition to a higher marine diet happened in the post-Roman period.

Chemical analyses of skeletal remains are therefore providing bioarchaeologists with information about the diets of individuals and of populations throughout the Empire, giving new insight particularly into the diet of lower-class Imperial residents. Finally, a newly published, open-access database of isotopes in the Greco-Roman world called IsoArcH is poised to generate breakthroughs in both palaeodiet and migration questions in the coming years (Salesse et al. 2017).

2. *Migration: How Were People Moving Around the Empire?*

The phenomenon of migration and its implication for the demographic structure of the Empire has previously been investigated through census records and inscriptions on tombstones. As the center of Imperial power, Rome itself had a great number of free immigrants and slaves who hailed from elsewhere. Identifying immigrants and slaves in the archaeological record has been challenging, however, because most were not noted as such in inscriptions or through artifact assemblages in graves. A major contribution of bioarchaeology in recent years has been the application of chemical techniques to identify population diasporas within the Empire.

Isotopes of strontium and oxygen are most commonly used to distinguish immigrants from locals in a skeletal assemblage. Strontium is incorporated into the human body during growth via groundwater, and the strontium isotope ratio derived from a human's dental enamel reflects

the geology of the area in which the person grew up. Lower strontium values generally indicate younger geology, such as volcanic areas, while higher values are indicative of older rock. Oxygen isotopes incorporated during tissue development are related to the overall climate of the area; lower values suggest a person grew up in a colder, wetter climate, and higher values suggest life in a warmer, drier climate. Some strontium and oxygen isotope studies have been done in the Roman Empire, but until significantly more data are available, interpretations are necessarily conservative in nature.

In the Roman suburbs, a strontium and oxygen study of dental enamel from the first molar, which forms between birth and 3 years of age, revealed numerous people who arrived at Rome from elsewhere (Killgrove and Montgomery 2016). Many of these immigrants to Rome apparently ate different diets as children, as the carbon isotopes demonstrated. Similarly, an oxygen isotope analysis of the first, second, and third molars from individuals buried at Portus Romae suggested a large chunk of the population moved there during childhood (Prowse et al. 2007), but work at Velia in southwest coastal Italy found no potential immigrants (Stark 2017). It is not currently possible to pinpoint an immigrant's homeland, but general trends in the data from Imperial Italy suggest that people were arriving in these cities from nearby areas such as the Apennines but also from areas with strikingly different geology and climate. Further, research on migration in the Roman suburbs suggests that the practice was not confined to young men, as there is ample evidence of immigrant women and children in the bioarchaeological record.

Migration did not occur just to Rome and to other large urban centers. In Southern Italy, a combination of oxygen isotope and ancient DNA analysis revealed an adult female with East Asian ancestry, whose burial form and grave goods otherwise did not indicate she originated elsewhere (Prowse et al. 2010). In the Romano-British burial ground of Spitalfields, a woman who was buried in a decorated lead coffin was shown through Pb isotope analysis to have originated in Rome (Montgomery et al. 2010). Several strontium and/or oxygen isotope studies have been conducted on Romano-British skeletal series in the past decade; by and large, they reveal a great deal of mobility in the area. At the sites of York, Gloucester, and Lankhills, for example, only about half of the people studied could be considered locals, while about 15–20% were from elsewhere in England, and 20–35% were long-distance migrants. Even far-flung areas like Aila in Jordan boasted immigrants during the Empire. A strontium study at that site found that the vast majority of people came from distant homelands, likely as workers to support its role as a trade center (Perry et al. 2017).

Isotope analyses of skeletal tissue are therefore yielding new information on patterns of migration within the Roman Empire as well as on the demographic makeup of both urban and rural settlements. Physical mobility within the Empire was quite high, and immigration was not by any means unidirectional. In many places, the importation of food and use of aqueducts complicates the interpretation of the isotope data. The reasons for population mobility are also still largely uncertain. Diasporas of people likely occurred with slavery and to a lesser extent with military service, but migration may also have been an option for families and for free individuals looking for work or for a spouse. The growing database of strontium and oxygen isotope data is revealing the great distances that people migrated in antiquity, and new applications of DNA analysis point the way forward for bioarchaeologists interested in contributing to the conversation about mobility and migration in the Empire. In the future, the challenge will be to integrate the scientific data drawn from chemical analyses of skeletons with the historical evidence from inscriptions and censuses to glean new information about the demographic fluctuations of imperial populations.

3. *Disease and Health: Who Got Sick in the Roman Empire?*

Only within the last 10 or 15 years have reports of trauma and disease in the archaeological record evolved from case studies of pathological conditions to large-scale research into the prevalence of

specific diseases in imperial populations. The recent debate on health in the Roman Empire starts with a look at systemic factors that may have increased people's stress, including urbanization, malnutrition, hygiene, and sanitation, as well as the comorbidity of various infectious diseases and parasites. The health of an individual and of a population is multifaceted, and researchers have employed skeletal remains from both Rome and Britain, in addition to primary and secondary source material, to argue that the Empire was not a particularly salubrious place to live.

Pathological data from several skeletal series in Rome have been published (e.g., Piccioli et al. 2015), although much of the information comes from incompletely analyzed skeletal series. Most research suggests that there were significant health stressors for people living in the city and suburbs, as evidenced by high frequencies of enamel hypoplasia and cribra orbitalia and by a decrease in overall stature during the Empire. Hypoplasias are defects in the formation of dental enamel and can be caused by a number of health issues, including malnutrition, disease, and weaning; cribra orbitalia is generally considered to result from iron-deficiency anemia, which in turn can be caused by nutritional deficiencies or disease; and variation in adult stature, particularly a trend in shorter stature, results when an individual is stressed during childhood, as from disease or malnutrition. In general, skeletal series from Rome show higher frequencies of enamel hypoplasia and cribra orbitalia and shorter stature than do series from Britain, likely owing to the urban nature of Rome, which had high population density and unequal resource allocation. Through time, the British skeletal series also provide evidence for a decrease in stature as well as increased exposure to anthropogenic lead in the Roman period. One suggestion for the decline in health during the Roman Empire is the presence of endemic malaria in the Mediterranean. Malaria in antiquity has been the subject of debate for a number of years; however, the skeletal evidence is still inconclusive, particularly since not all Roman skeletal series show high frequencies of cribra orbitalia. Currently, understanding disease frequencies around the Empire is complicated by the lack of standardization in data collection practices, by the lack of analyses of large cemetery series, and by the focus on individuals and on specific, unusual pathologies (Killgrove 2017, 2018).

DNA analysis may present a way forward in studies of disease in the Roman Empire, although this technique is still very new. Using pathogen DNA analysis to identify the genes of organisms responsible for disease, recent research has discovered evidence of malaria in two individuals who lived in Italy during the early Empire (Marciniak 2016; Marciniak et al. 2016), has found a case of leprosy outside of Rome in the middle Empire (Rubini et al. 2014), and has determined that the cause of the Justinian plague in the sixth century CE was the same organism that caused the Black Death centuries later (Wagner et al. 2014; Harbeck et al. 2013). While pathogen DNA analysis is still time-consuming and expensive, it is likely that in the coming years, technology will advance and lower these barriers to testing Roman remains. A complementary technique is paleoparasitology, in which ancient soil or sewage is microscopically examined for evidence of parasite eggs. This technique so far has produced widespread evidence of roundworm and whipworm in the Roman Empire (Mitchell 2017; Dufour et al. 2016) as well as the protozoan *Giardia* (Williams et al. 2017).

In spite of these advances, it remains difficult to fully understand morbidity and mortality in a population, as they are complicated processes dependent on a variety of environmental and sociocultural factors. With few fully published skeletal series outside of Roman Britain, the disease ecology within the Empire as a whole is still largely unknown. Research that synthesizes the available historical and osteological information on population size, sanitation, nutrition, and disease is becoming more common in bioarchaeological research in general, opening up a worldwide discussion about health and disease in antiquity (e.g., Harper 2017; Scheidel 2018). Combined with the growing use of chemical techniques to identify pathogens, bioarchaeological research is beginning to

produce novel information about health in the Roman Empire.

4. *International Outreach*

The international picture of Imperial Roman bioarchaeology in the twenty-first century is considerably wide ranging, although still concentrated largely on Italy, Britain, and Greece, which have produced a wealth of skeletal remains in the past few decades. In the former Roman provinces, work is underway in Aegyptus, Arabia Petraea, Africa Proconsularis, Dalmatia, Gaul, Germania, Hispania, and Asia Minor, to name a few. Although the population of bioarchaeological practitioners has diversified since the end of the twentieth century, British researchers remain at the forefront of the field, thanks to large skeletal series such as Poundbury Camp and cutting-edge technology. The bioarchaeology of Roman Britain is yielding in-depth reports on paleopathology, demography, mobility, and diet. These techniques are just beginning to be applied in Italy at Rome, at circum-Vesuvian sites, and at suburban and rural sites by Italian researchers affiliated with the archaeological superintendencies and universities and by European and North American scholars. Although there is not yet an international database of Roman skeletons, a movement toward data sharing and open access is underway in American biological anthropology, which will pave the way for synthetic treatments of bioarchaeological information by its international creators. Additional data are starting to come out in the form of 3D scans and photogrammetric models produced by Roman bioarchaeologists and archaeologists.

In this age of digital connections, however, information on classical bioarchaeology is being shared across linguistic divides not just at international conferences but also through social networking, newsgroups, blogs, and interdisciplinary journals. This includes academic researchers writing about classical history and archaeology news, for instance, Kristina Killgrove and Sarah E. Bond both write online columns at Forbes.com. Additionally, a multitude of other blogs and websites exist as Roman bioarchaeology moves to embrace the digital humanities and public outreach.

Future Directions

The past decade has seen bioarchaeological research expand from the core of the Roman world to the lesser-investigated provinces of the Empire. More work is needed, however, in places like Hispania, Gaul, Illyricum, Asia Minor, Syria, and Judaea. The city of Rome itself has produced thousands of skeletons in recent years, but most cemeteries remain at least partially unpublished, making synthetic treatments challenging at the moment. Future studies at both the center and periphery of the Empire will make it easier to understand the diversity of the heterogeneous peoples who comprised the imperial population.

Moving forward, Roman bioarchaeologists will be able to address research questions about disease ecology, identity formation, and population interaction. Paleopathological research has primarily been focused on identifying diseases in the skeletal record of the Roman Empire, but more could be done to understand the ecology of those diseases. In Rome, for example, wildly varying frequencies of skeletal markers of stress and infection suggest living in different areas of the city and suburbs put people at different risk for diseases such as malaria. Investigating the topography, climate, and water sources of Rome is just as important as doing macroscopic and chemical analyses of skeletons for understanding morbidity patterns, and a bioarchaeological approach that incorporates disease ecology will move the study of Roman health forward.

Isotope and DNA analyses have already yielded key information about migration within the Roman Empire, by isolating individuals who traveled to and from Italy during their lifetimes. These data, however, have seldom been used to draw conclusions about identity formation in the multiethnic Empire, which would be a key step forward for Roman bioarchaeology. Pushed even further, data from chemical analyses combined with material remains and demographic models may allow Roman bioarchaeologists to investigate the practice of slavery in a novel manner. With more isotope analyses and additional DNA

studies, a bioarchaeological approach to understanding Roman slavery cannot be far off.

Almost 40 years ago, Colin Renfrew (1980: 297) wrote that there was a place "for anyone who can command the data and the scholarship of the Great Tradition while employing the problem-orientation and the research methods of current anthropological archaeology." Bioarchaeologists who work in the Roman Empire have taken up this challenge and are weaving together scientific and humanistic data on a daily basis. Roman archaeology has already benefitted immensely from a bioarchaeological approach that integrates textual, artistic, and other material evidence with biological remains to create a more holistic picture of all levels of life and culture in the Roman world.

In the past decade, bioarchaeological research in the Roman Empire has surged from basically nothing to an active international research program tackling difficult questions about diet, disease, and demographics from a scientific standpoint. Bioarchaeologists in the Roman world have only recently begun to reflect on the accumulated data, yet bioarchaeological approaches have already clearly demonstrated that the Roman Empire was a strikingly diverse place. Heterogeneous groups of people from different homelands lived in cities, rural outposts, and forts on the *limes*. Their diets were composed primarily of cereals, meat, and plants, but the proportions of these resources and the types consumed differed dramatically. The people likely differed biologically in their risk of mortality and culturally in their attempts to mitigate disease and induce health. The last decade of research has demonstrated that literature is a great way of framing life in the Roman Empire but that bioarchaeology is necessary to complete the picture.

Bioarchaeology, Human Osteology, and Forensic Anthropology: Definitions and Developments

Douglas H. Ubelaker
National Museum of Natural History,
Smithsonian Institution, Washington, DC, USA

Introduction and Definition

The analysis and interpretation of human skeletal remains focus largely on what can be learned from these remnants, as well as the individuals and populations they represent. The terms bioarchaeology, human osteology, and human skeletal biology all refer to scholarly inquiry in this area, but each conveys a distinct emphasis. Osteology represents the most traditional term used, with its accent on comparative morphology. Skeletal biology also refers to comparative morphological study but recognizes the dynamic nature of skeletal growth and maintenance, as well as biomechanical and environmental factors that shape bone morphology. Bioarchaeology includes all of the above but focuses on remains recovered from archaeological contexts with special consideration to the associations of biological and cultural factors.

Historical Background

The academic roots of this discipline extend back primarily to Europe and Asia with an interest in the evidence for human evolution (paleoanthropology) linked with the recovery of ancient human remains. The early discovery and interpretation of fossil hominids required knowledge of comparative skeletal anatomy. Such

perspective could be ascertained from collections of modern human remains recovered from archaeological contexts.

Although some human remains were recovered through construction activities and other accidental encounters, increasingly, collections were assembled from systematic archaeological excavations. Such excavations not only yielded human skeletal material but usually abundant associated cultural information as well. This information frequently enabled the remains to be dated and placed in cultural context. As these collections grew in number and size, they facilitated the development, growth, and evolution of the discipline.

Academic interest in skeletal analysis during the nineteenth century focused largely on the skull with the general belief that it presented the primary evidence for the topics of research at the time, including human variation and documentation of regional physical types. The evidence for disease was also of interest due to the medical background of many of the field's practitioners.

A key historical development in the emergence of human skeletal biology was the 1855 formation of the Society of Anthropology of Paris by Paul Broca (1824–1880). A surgeon by profession and an expert in neuroanatomy, Broca called together key professionals in the fields of medicine, anthropology, archaeology, and related areas to focus on academic advancements relating to the interpretation of human skeletal remains. This effort led to the development of measuring techniques, instrumentation, and training. Most importantly, it provided a forum for scholarly discussion and interaction, with a stress on human skeletal anatomy and its interpretation.

Shortly thereafter (1861), German physical anthropologists gathered in Göttingen for scientific interaction and to discuss standardization of methodology. Subsequent meetings led to the 1866 formation of the journal Archiv für Anthropologie, a publication later sponsored by the Deutsche Gesellschaft für Anthropologie (DGA). Prior to that time, the noted German scientist Johann Friedrich Blumenbach (1752–1840) had assembled large international collections of human remains in Göttingen. Other large nineteenth-century German collections were organized by pathologist Rudolf Virchow (1821–1902) in Berlin and Alexander Ecker (1816–1887) in Freiburg. German efforts to promote standardization in methodology led to the 1882 Frankfort agreement in which the Frankfort horizontal was defined, a standard for cranial orientation still of universal acceptance today. Another key contribution consists of the 1914 publication of Lehrbuch der Anthropologie, written by Rudolf Martin (1864–1925), which contained a detailed presentation of standard techniques of analysis.

The developments in France and Germany described above were echoed in varying ways throughout Europe and other areas of the world in the nineteenth and early twentieth centuries. Globally, academics assembled collections of human remains, developed scholarly organizations and publications, and initiated training programs. Research inquiries continued to conform to those established in the early nineteenth century.

Aleš Hrdlička (1869–1943) represents a key figure in the historical development of human skeletal studies in the Americas. An 1881 immigrant from Bohemia (now the Czech Republic) to the United States, Hrdlička assembled large collections of human remains at the Smithsonian Institution in Washington, D.C. Although medically trained, he had studied in Paris with Broca and developed a strong interest in anthropology. His own 1920 publication *Practical Anthropometry* complemented Martin's work and contributed to the standardization of methodology. He also founded the American Journal of Physical Anthropology in 1918 and later the American Association of Physical Anthropologists in 1930.

By the mid-twentieth century, scholarly institutions around the world had assembled large collections of human remains, developed standard approaches for recording data, initiated training programs, and inaugurated publication programs with a strong focus on comparative human osteology. Much of the goal of this effort was to collect skeletal data in a standard format to

facilitate comparative studies. Compilations of measurements and observations frequently were presented as appendices to archaeological reports and tabulated in monographs. Throughout these advancements in comparative studies, work within the field remained tied to its traditional topics of investigation.

As data and collection sizes grew, researchers, particularly in North America, gradually recognized the value of a more problem-oriented approach to skeletal analysis and interpretation. Although comparative morphological studies continued, researchers began to emphasize the dynamic nature of bone growth, development, and maintenance. This emphasis led to studies of bone remodeling, histological age changes, details of bone response to disease insult, and environmental influences. Biomechanical factors were considered in more elaborate research designs that evaluated bone strength and stress factors. Skeletal collections continued to be regarded as reservoirs of information on past population relationships. However, a new emphasis appeared, recognizing that bone morphology also reflected factors of the environment, nutrition, disease, and human behavior, including occupation/habitual use of the skeleton. This perspective is generally reflected in the shift to use of the term "skeletal biology" to define the field. Sorting out the factors of genetics and environment on skeletal morphology became a major issue and subject of research.

A related key historical development involves strengthening of statistical rigor in analysis of skeletal morphology. Much of this effort can be traced to the biometric school established by Karl Pearson (1857–1936) in 1903. Enhanced statistical treatment of skeletal biology data enabled more robust interpretation and assessment of the probabilities involved.

The general trend toward more problem-oriented studies also stimulated novel methods of recording data and observations. These were designed to address specific research issues and moved away from the standardized approaches previously adhered to.

Key Issues/Current Debates

The use of cranial indices and recognition of cranial variation gradually gave way to biological distance studies. These problem-oriented approaches also recognized the genetic component in skeletal, especially cranial, morphology but utilized large, well-documented samples and statistical analyses that presented the variation and probabilities involved. The traditional use of cranial measurements continued and enhanced with observations of discrete traits on the skeleton, dental measurement, and dental observations. Very recently, distance studies have included three-dimensional shape analysis made possible by sophisticated computer software and new instrumentation. These approaches not only enabled a more powerful and revealing look at likely population relationships of the past but also a more nuanced presentation of the variability involved. The recent amplification and analysis of ancient human DNA recovered from archaeological contexts provide modern perspective on past population relationships.

Many of the areas of new interest in skeletal biology relate to the realization that the non-genetic influences on skeletal morphology present opportunities for expanded research. Historically, those interested in using cranial morphology to assess human variation either ignored environmental influences or regarded them as undesirable factors detracting from the research mission. However, others emphasized that these influences presented valuable information on human behavior, adaptation, occupation, and habitual posture. This functional orientation also had deep roots, especially in Germany with the work of Virchow, Julius Wolff (1836–1902), and others. These early researchers recognized the relationship between structural features of bone and the nature of the external stresses/forces acting upon it. Investigators in more modern times built upon the knowledge advanced by these early workers to examine cross-sectional geometry, patterns of trauma, and arthritic alterations as well as other indicators of musculoskeletal stress. Bones are shaped by how

they are used; thus, shape analysis potentially reveals information on use.

Routine analysis of remains from archaeological contexts calls not only for detailed inventory but also estimates of sex and age. Methodology for the estimation of sex and age continues to evolve and recognizes the dynamics of growth and development as well as human variation in the expression of sexual dimorphism and the process and timing of adult aging. Data on the age and sex distribution of skeletal samples have led to advances in the field of paleodemography.

Modeled after the demographic study of living populations, paleodemography utilizes age and sex information to construct life tables, mortality curves, survivorship curves, and related expressions of demographic profiles. Such formulations produce valuable projections of life expectancy, age-specific mortality, and similar statistics of past populations that can be compared with those of modern times. However, procedures in this field have sparked lively debate, especially regarding the accuracy of age estimation and sampling issues.

Paleopathology has remained an area of interest throughout the history of skeletal inquiry. Much of the early history of paleopathology studies focused on the evidence for and history of specific diseases, especially leprosy, tuberculosis, and syphilis. Such interest has been sustained and continues today. Modern developments include more sophisticated models of differential diagnosis, improved documentation of studied samples, and new molecular approaches aimed at identification of specific pathogens.

A significant development also has been a population approach to the study of disease. Termed paleoepidemiology, this approach consists of examining the prevalence of expressions of mortality in the past, especially viewed in cultural, geographic, and temporal context. This research focus departs from attempts to diagnose particular diseases in favor of gathering population data on categories of disease/morbidity that reflect such factors as population size and density, diet, nutrition, sedentism, and sanitation. Such research has proven especially valuable in examining long-term temporal trends of morbidity and mortality in specific regions of the world. The endeavor is closely linked with the methodology and results of paleodemography and regional studies of adaptation, including those in archaeology. Research in this area also has addressed quality of life factors and added thoughtful perspective to traditional analyses.

The term bioarchaeology emphasizes the integration of biological information gleaned from skeletal analysis with the cultural/archaeological information available from the provenience. This term recognizes the nature of many of the large skeletal collections throughout the world and their known archaeological contexts. Data on sex, age at death, disease alterations, cultural effects on the skeleton, estimates of living stature, and other biological variables can be correlated with cultural mortuary site information when working with well-documented collections. Such research enables studies of status, gender roles, social relationships, and factors contributing to mortuary site complexity. In broader context, related studies contribute to understanding of dietary adjustment, environmental adaptation, demographic patterns, migration, and regional disease expression. Such studies are completely dependent on sufficient archaeological documentation, not only regarding burial provenience but site and regional complexity as well.

Advances in the discipline of bioarchaeology depend extensively not only on the availability of adequate documented collections but also appropriate interpretive models and methodology. Methodology has grown increasingly technological and sophisticated in recent decades. Early studies in this discipline focused primarily on procedures and instruments to manually gather data. This approach recognized the interests of the time but also the limitations of data analysis. Data synthesis was limited by what could be processed using adding machines and simple calculations. In more recent times, computers have enabled sophisticated approaches including the formulation of large databases and complex statistical analyses.

Technological advances in other areas have also opened up new approaches to research. Advances in microscopy and thin-section preparation brought histological analysis into prominence within the discipline. Impacts were especially evident in methodology for age at death estimation and disease diagnosis. Scanning electron microscopy facilitated studies of microwear on occlusal tooth surfaces, contributing to interpretations of diet and the use of teeth as tools. Radiocarbon dating enabled more exact chronological placement of skeletal collections and improved interpretation of the associated cultural information. In forensic anthropology, radiocarbon analysis with reference to the modern bomb curve also has facilitated time since death determination.

Dietary reconstruction became possible through analysis of elemental isotopes and trace elements. In particular, the isotopes of carbon, nitrogen, hydrogen, oxygen, and strontium potentially reveal dietary food chain information. Carbon isotope analysis has been used to identify consumption of plants with distinct photosynthetic pathways. The availability of dietary information enabled the use of more sophisticated bioarchaeological studies of associations of disease, diet, and environmental context. These in turn could be related to paleodemographic information for a more holistic approach to understanding past populations.

Radiographs and X-ray technology in general have proven very important for skeletal biology research. Radiographic techniques have enabled nondestructive studies of mummified remains and a more sophisticated analysis of skeletal structure. Examples include recognition and interpretation of lines of arrested growth in long bones, patterns of cortical thickness in studies of age change and cross-sectional biometrical analyses, and trauma interpretation. Recent computerized tomography (CT) scan technology has improved the precision of such analysis and offered three-dimensional approaches.

Forensic anthropology shares many of the techniques of other areas of skeletal biology but includes some methods that are unique to its own field. Forensic anthropology refers to the application of knowledge and methodology in physical anthropology to medicolegal problems. Such problems usually involve identification of recovered human remains and deciphering what happened to them. This interpretation consists of determining if recovered evidence represents skeletal or dental tissue; recognizing species; estimating age at death, sex, living stature, time since death, and ancestry; evaluating evidence for identification; assessing postmortem alterations (taphonomy); and interpreting any evidence for foul play.

The history of forensic anthropology closely follows that of skeletal biology/osteology in general with a stronger North American focus. The academic roots extend back to early European pioneers but much of the development occurred in North America as a response to needs within the medicolegal community. Although Aleš Hrdlička was involved in some forensic application, his successors in the United States, T. D. Stewart (1901–1997), J. Lawrence Angel (1915–1986), Wilton Krogman (1903–1987), Mildred Trotter (1899–1991), Ellis R. Kerley (1924–1998), William M. Bass, Clyde Snow (1928–2014), and others, provided momentum. Key administrative developments include the formation of the Physical Anthropology Section of the American Academy of Forensic Sciences in 1972 and the American Board of Forensic Anthropology in 1977. The former provided an annual forum for discussion and presentation of research results in forensic anthropology. The latter offered a certification program for qualified forensic anthropologists who had a Ph.D. degree and experience and could pass a written and practical examination. In 2017, membership of all types in the anthropology section of the AAFS totaled 538 and 117 forensic anthropologists had been awarded diplomate status by the ABFA.

Global interest in forensic anthropology has strengthened in recent years due to augmented

training programs, growing recognition of the value of incorporating forensic anthropological perspective with medicolegal initiatives, and the investigation of human rights issues. Anthropologists are especially needed in recovery efforts and have been utilized extensively by such organizations as the International Commission on Missing Persons (ICMP), the International Committee of the Red Cross (ICRC), the Argentine Forensic Anthropology Team (EEAF), and many others.

Work in forensic anthropology relates very closely with other areas of skeletal biology. Most of the techniques of human skeletal biology are needed in the analysis of human remains in a forensic context. Information garnered from forensic analysis and research improves interpretation in the more general field of skeletal biology, especially in regard to trauma interpretation.

Future Directions

From its inception, the discipline has been dependent on the availability of well-documented collections of human remains throughout key areas of the world. Through the work of pioneers like Blumenbach, Virchow, Hrdlička, Samuel Morton (1799–1851), Bass, and many archaeologists worldwide, documented collections of human remains have been compiled and made available for research. These assemblages include key reference collections of individuals, whose age at death, sex, and partial life histories are documented, providing a strong foundation for the development of methodology. The bulk of the collections are from archaeological contexts and store the information about past lives and living conditions that can potentially be made available through research. Further advances in the field are dependent upon their growth and continued availability to researchers.

Fortunately, well-documented collections continue to be assembled worldwide. This development reflects the growing recognition of how much can be learned from them and how vital that knowledge is to forensic applications, justice, and understanding of the human condition, past, and present. In addition, these collections are originating from previously underrepresented areas of the world. They provide new perspective on human variation in all of the science areas investigated. They also allow regional development of methodology that meets the needs of anthropologists working in the area.

In contrast, some areas of the world have witnessed developments regarding repatriation and/or other constraints on the growth of skeletal collections. A strong expression in this development has occurred in the United States through policies and laws that affect continued curation of some collections of human remains. In the United States, many collections relating to the American Indian communities, including some of great antiquity, have been transferred to American Indian groups desiring custody. Similar developments have occurred in Australia and other parts of the world on a lesser scale. Likewise, policies and laws have also affected the disposition of recently recovered ancient human remains, limiting growth of new collections.

While these developments appear to restrict future expansion and maintenance of some collections in particular world areas, they also have stimulated systematic data collection. Recognizing that the affected collections may not be available to future researchers, thoughtful protocols have been developed to capture key measurements, observations, and images that likely will be useful for future research. These initiatives have stimulated attempts to develop standards for data collection, reminiscent of the efforts by the early pioneers of Broca, Martin, Hrdlička, and others. With the availability today of computer technology, large databases can be assembled that will hopefully facilitate the work of future physical anthropologists.

The discipline has evolved extensively over the centuries and continues to change. The future appears bright as many highly motivated and intelligent students continue to enter the field,

especially in the areas of paleopathology and forensic anthropology. New technology and improved interpretive models enable novel issues to be addressed, with growing applications in forensic anthropology. Research has become increasingly interdisciplinary, frequently involving teams of specialists. The early pioneers would be amazed at how far this field has advanced but likely pleased that their work enabled so much of the progress to be made.

Bioarchaeology: Definition

Clark Spencer Larsen
Department of Anthropology, The Ohio State University, Columbus, OH, USA

Brief Definition of the Topic

Bioarchaeology is the study of human remains from archaeological contexts. Although the term was first used in reference to the study of animal remains, it has generally become exclusive to human remains, but sometimes called human osteoarchaeology or human bioarchaeology. The field emphasizes integrative, interdisciplinary analysis of the links between biology and culture in past societies. This approach has contributed to an informed understanding of the range of social, behavioral, and economic conditions and circumstances that have shaped the human experience – especially health and well-being, lifestyle, and quality of life – during the last 10,000 years of human evolutionary history.

Biological Distance in Bioarchaeology and Human Osteology

Michael Pietrusewsky
Department of Anthropology, University of Hawaii at Manoa, Honolulu, HI, USA

Introduction

Biological distance, or biodistance, is a measure of relatedness or divergence among groups separated by time and/or geography based on morphological variation (Buikstra et al. 1990). Biological distance studies, which are undertaken to reconstruct population history and to assess ancestry, dominated bioarchaeological research during the nineteenth and early twentieth centuries. The earliest attempts to comprehend human variation and measure relatedness among human groups, through the construction of typological racial classifications, fell short of their predicted goals. These early attempts, which led to the mistaken belief that humanity could be divided into a finite number of pure races, were flawed in theory and method. Advances in evolutionary theory, including quantitative and population genetics, and improvements in computing and statistical procedures in the early twentieth century provided a much firmer foundation for measuring and interpreting morphological variation within and between human groups.

Because of the demonstrated correlation between phenotypic and genotypic similarities, measures of biological distance in bioarchaeology are generally determined through the application of quantitative methods to metric and nonmetric variation recorded in skulls, teeth, and skeletons. Ancient DNA (aDNA) and other biochemical and geochemical traits are relatively new additions to biodistance studies.

Studies of cranial form, most notably cranial measurements (or craniometrics) that quantify morphology, figured prominently in the early development of the discipline and continue to occupy a central role in modern biological distance studies today. While morphological variation, especially quantitative variation, is subject to nongenetic or environmental influences, this category of variation is generally assumed to reflect genetic similarity resulting from neutral evolutionary forces (genetic drift, gene flow, and mutation). There is now an emerging consensus that craniometric data can be used as a proxy to genetic data, hence the popularity of this category of variation in biodistance studies. Teeth, especially dental nonmetric traits, have also figured prominently in assessing biological distance among ancient and modern populations. Standardization of dental scoring methods, the high genetic component, and the conservatism of this category of variation have made the dentition a popular choice for reconstructing population history.

Mathematically based methods, which are often based on quantitative and population genetic analyses, allow bioarchaeologists to address a broad array of research topics that include:

- Estimating biological relationships, temporally and spatially, for reconstructing the structure and history of past populations, origins, and human dispersals (e.g., Byrd 2014).
- Investigating microevolutionary processes (e.g., gene flow, genetic drift, selection) and the influence of geography and other isolating mechanisms on the observed patterns of biological relatedness (e.g., Smith 2011).
- Identification of postmarital residence patterns, familial and kin groupings, cemetery structure, social status, immigrants, and admixture (e.g., Cook and Aubry 2014; Stojanowski and Schillaci 2006).
- Sorting of commingled skeletal and dental remains and assignment of an unknown individual (or skull) to a known reference group in repatriation claims and forensic cases (e.g., Ross et al. 2016; Seidemann et al. 2009).
- Provide an important context for addressing other topics in bioarchaeology such as paleopathology, paleodemography, health, diet, etc. (e.g., Sutter and Verano 2007).

Definition

Biological distance, or biodistance, through the application of multivariate statistical procedures to metric and nonmetric skeletal/dental traits, is a measure of biological relatedness (similarity/dissimilarity) among populations separated by time and/or geography (Buikstra et al. 1990).

Key Issues

Although equally applicable to morphological/phenotypic variation, the discussion of the key issues in biological distance studies will focus on the use of cranial measurements, or craniometrics, unless otherwise noted.

Underlying Assumptions

While phenotypic, including craniometric, variation is subject to nongenetic or environmental influences (e.g., diet and climate) and past diversifying selection, there is overwhelming consensus that this category of variation generally reflects underlying genotypic variation. Those groups that display more phenotypic similarity are more closely related than those that do not. Furthermore, a number of studies have demonstrated that human cranial morphology, including craniometry, is moderately heritable, which strengthens their use in biodistance analyses (e.g., Sjøvold 1984; Carson 2006; Martínez-Abadías et al. 2009).

Geographic Patterning and Neutrality of Craniometric/Phenotypic Variation

Beginning with the pioneering work of W.W. Howells (1973), there is now near universal acceptance that human cranial variation is geographically structured making it highly attractive for reconstructing population history and for assessing ancestry.

While some aspects of cranial morphology may be influenced by climate (Hubbe et al. 2009) and subsistence (e.g., von Cramon-Taubadel and Pinhasi 2011), various lines of evidence have demonstrated that neutral evolutionary forces (e.g., mutation, gene flow, and genetic drift) primarily shape global patterns of human phenotypic and cranial variation under an isolation by distance model (Harvati and Weaver 2006; Relethford 2004; Roseman 2004; von Cramon-Taubadel 2009, 2014; Betti et al. 2010). The adoption and application of an explicit microevolutionary framework based on population genetic theory in the analysis of phenotypic data allows the effects of past gene flow, genetic drift, and natural selection to be modeled thus allowing cranial variation to be used as a proxy for genetic data estimating population structure and history. Additionally, because craniometric variation is geographically structured, high levels of classification accuracy are achievable when crania from different parts of the world are compared (Relethford 2009).

Categories of Data and Traditional Morphometric Methods

Two main categories of data, metric and nonmetric, have been traditionally associated with biodistance studies in bioarchaeology and human osteology. Metric data includes measurements recorded in the skull, postcranial skeleton, and teeth. Measurements (e.g., linear measurements, arcs, subtenses, and indices) represent continuous variables traditionally recorded using calipers in traditional morphometrics or, Cartesian coordinates of anatomical landmarks recorded using 3-D digitizers in geometric morphometrics nonmetric traits represent discontinuous or discrete variables (e.g., metopic suture, os inca, shovel-shaped incisors) that are recorded on a presence/absence basis or some gradation from absence to complete expression of the trait. More recently, a third category of data for use in biodistance studies is recognized, ancient DNA. The precision and relative ease of recording metric and nonmetric data as well as the noninvasive nature of the technique have promoted the use of metric and nonmetric data in the genomic and post-NAGPRA age. The Native American Graves Protection and Repatriation Act (NAGPRA), which was enacted in 1990, is a federal law in the United States that requires federal agencies to provide opportunities for federally recognized American Indian tribes and Native Hawaiian organizations to obtain

(and often repatriate) culturally affiliated human remains and artifacts.

Studies of biological distance, beginning in the 1970s, increasingly relied on the application of multivariate statistical procedures to craniometric data. Multivariate statistical procedures comprise a family of related mathematical procedures that allow the simultaneous analysis of many random but interrelated variables whose effects cannot be interpreted individually in a meaningful manner. These procedures are exceptionally well suited for investigating patterns of biological variation, measuring relatedness among groups, and making other inferences of the variables and groups selected. The primary multivariate statistical procedures applied to craniometric traits in biological distance studies include principal components analysis, stepwise discriminant function (canonical) analysis and Mahalanobis generalized distance. Various clustering algorithms, such as the unweighted pair-group method using arithmetic averages (UPGMA), facilitate interpretation of relatedness between groups through the construction of dendrograms (see section "An Example of Biological Distance Analysis"). C.A.B.. Smith's Mean Measure of Divergence (MMD) remains one of the most popular distance statistics for analyzing dental and cranial nonmetric traits.

Because most multivariate procedures, such as Mahalanobis distance, require complete sets of data, missing measurements must be replaced by various estimation methods. Replacement of missing data can only be applied when a few measurements (per individual) are missing. This means only complete or nearly complete crania can be ultimately selected for analysis using multivariate statistics. An alternative strategy is to reduce the number of variables (measurements) entered into the analysis. A more detailed discussion of the methods used for analyzing metric data is provided in Pietrusewsky (2008a).

In addition to traditional landmark measurements (e.g., linear distances, areas, volume, angles), the use of Cartesian coordinates of cranial landmarks recorded in two or three dimensions using digitizing equipment is a recent alternative approach for quantifying size and shape. Geometric morphometric techniques, including Procrustes analysis, have become standard tools for analyzing coordinate data (Slice 2007).

B

Continuing Interest in Cranial Shape and Craniometrics

The popularity and justification for the continued use of traditional morphometric data and analysis in bioarchaeology, human osteology, and forensic anthropology is supported by a number of factors. Chief among these are the standardization, ease of recording, precision, cost effectiveness, and repeatability of the methods involved with the recording of craniometric data. Also, the conservative nature, direct link to the past, amenability to analysis using multivariate statistical procedures, the existence of a heritability component, strong geographic patterning, and selective neutrality make this category of variation ideal for use in biodistance studies. Compared to geometric morphometric data, the statistical analysis and computer technology associated with traditional morphometric data is less daunting than that associated with geometric morphometrics. The recent restrictions imposed on human DNA studies and loss of skeletal collections due to repatriation make existing data archives (e.g., Howells' Craniometric Data) incalculable for future biodistance research.

Model-Free and Model-Bound Approaches

The earliest biological distance studies were largely model free approaches that focused more on the overall similarities among groups than on the causes of the observed patterns of variation. Later studies applied a population genetic framework for analyzing quantitative traits (e.g., Relethford and Blangero 1990; Roseman 2004; Smith 2011). These model-bound approaches allowed the estimation of microevolutionary processes such as gene flow, genetic drift, etc. However, because some model-free approaches (even though they do not involve formal estimation of model parameters) are based on population genetic models (i.e., isolation-by-distance model), the distinction between model-free and model-bound approaches to understanding population

structure and history is not always clear (Relethford 2016).

Selection of Samples and Variables

Because skeletal series represent only samples of past biological populations, which often span considerable periods of time and may be biased in their representation, extreme caution should be exercised when skeletal (cranial) samples are used in biological distance studies. Using relatively large samples that are free of systematic bias helps to alleviate some of the concerns. Likewise, the selection of traits that are less susceptible to environmental and cultural influences further insures that the results of biological distance analysis more closely estimate genetic relatedness.

Some Current Topics

Origin and Dispersal of Modern Humans/ Primate Evolution

Refinements in methods and techniques continue to influence work in biological distance studies. Some of the recent studies involving quantitative cranial phenotypic data are associated with testing modern human out-of-Africa dispersal models and the implications these have for the origin of anatomically modern humans (e.g., Reyes-Centeno et al. 2015). The association of craniometric variation and geography has been viewed within the context of this larger debate. The question of whether long distance gene flow mediated by geographic distance (isolation by distance model) or population dispersal such as with the spread of modern humans out of Africa 100–150,000 years ago is responsible for this observed correlation, have been examined (e.g., Weaver et al. 2008). Biological distance studies have also been used in the reconstruction of phylogenetic relationships in the primate fossil record (Smith and von Cramon-Taubadel 2015).

Peopling of the Americas

Studies in biological distance contribute to reconstructions of population history at both the global and regional levels. Craniometric studies that address the peopling of the Americas are illustrative of regional analysis (e.g., von Cramon-Taubadel et al. 2017). Many other studies examining the population history of various regions and time periods, too numerous to cite in this entry, have appeared in the literature in recent years.

Transition from Hunting-Gathering to Agriculture

Another debate that biological distance studies have contributed to in recent years is the transition to farming in Europe and whether indigenous hunter-gatherers were replaced (demic diffusion model) by agriculturalists from the Near East or whether these indigenous groups adopted farming practices (cultural diffusion model) from their neighbors (e.g., Hubbe et al. 2009; Paschetta et al. 2016; Pinhasi et al. 2015; von Cramon-Taubadel et al. 2013). Studies that focus on the transition to farming in other regions of the world have also appeared.

Boas' Immigration Studies and Cranial Plasticity/Climate and Environmental Influences

Several recent investigations (e.g., Jantz and Logan 2010) examined the statistical and biological significance of Franz Boas' immigration studies as they relate to cranial plasticity. Often these studies are discussed within the broader context of the debate over genetic and environmental influences on craniometric variation and the degree to which skeletal and dental morphology are influenced by environmental and/or selection pressures (e.g., Betti et al. 2010; González-José et al. 2005; Harvati and Weaver 2006; Hubbe et al. 2009; von Cramon-Taubadel et al. 2013).

In the field of forensic anthropology, discussion continues over the existence of races and the use of computer software programs (e.g., FORDISC and CRANID) designed to assigned unknown individuals to a reference group (e.g., Jantz and Ousley 2005; Wright 2010).

Regions of the Skull and Biodistance Studies

Several recent studies have identified the possible influence of environmental factors that may affect cranio-facial morphology. These, in turn, have led

Biological Distance in Bioarchaeology and Human Osteology, Table 1 Fifty-six male cranial samples used in the example

Sample (abbrev.)	No. of crania	Location[a] and number of crania	Remarks
Polynesia			
1. Tonga-Samoa (TOG)	19	BER-3; AMS-2; DRE-1; PAR-1 BPB-4; AIM-2; AUK-5; SIM-1	Fourteen specimens are from Tonga and five are from Samoa. Included in the Tongan series are three skulls from Pongaimotu excavated by McKern in 1920; two from To-At-1 and To-At-2 excavated by Janet Davidson in 1965; and five from To-At-36 excavated by Dirk Spennemann in 1985/1986. The remaining specimens are from museums in Berlin, Paris and Sydney. The skeletons from the three burial mounds (To-At-1, To-At-2, and To-At-36) date to the Chiefdom Period in Tonga (460-0 cal BP). Although the exact dates for the remaining crania are not known, the majority are believed to be prehistoric
2. Easter Island (EAS)	50	BER-5; DRE-9; PAR-36	Pinart collected most of the crania in Paris in 1887 at Vaihu and La Perouse Bay, Rapa Nui (Easter Island). The exact dates of these specimens are not known
3. Hawaii (HAW)	60	BPB-20; HON-20; SIM-20	An equal number of specimens have been randomly chosen from three different skeletal series: Mōkapu (O'ahu), Honokahua (Maui), and Kaua'i. All specimens are presumed to be prehistoric (pre-1778)
4. Marquesas (MRQ)	63	PAR-49; LEP-1; BLU-1; BPB-12	Crania are from four islands, Fatu Hiva, Tahuata, Nuku Hiva and Hiva Oa. The exact dates of these specimens are not known
5. New Zealand (NZ)	50	BRE-3; PAR-21; SAM-1; AIM-13; GOT-1; ZUR-5; DRE-6	A representative sample of New Zealand Maori crania from the North and South Islands of New Zealand. The exact dates of these specimens are not known
6. Chatham Islands (CHT)	45	DUN-8; OTM-2 WEL-4; CAN-10 AIM-3; DRE-5 AMS-2; DAS-3 GOT-4; PAR-4	Moriori crania from the Chatham Islands, New Zealand. The exact dates of these specimens are not known
7. Society Islands (SOC)	44	PAR-33; BPB-11	Crania are from the island of Tahiti, Society Islands. The exact dates of these specimens are not known
8. Tuamotu Archipelago (TUA)	18	PAR-18	The majority of the specimens are from Makatea in the Tuamotu Archipelago. The exact dates of these specimens are not known
Island Melanesia			
9. Fiji (FIJ)	42	BER-1; SAM-3 ; QMB-1; DRE-4 FRE-3; CHA-1; BPB-11; PAR-7 AMS-3; DUN-6; SIM-2	Crania are from all major islands including the Lau Group in the Fiji Islands. The exact dates of these specimens are not known

(continued)

Biological Distance in Bioarchaeology and Human Osteology, Table 1 (continued)

Sample (abbrev.)	No. of crania	Location[a] and number of crania	Remarks
10. Vanuatu (VAN)	47	BAS-47	Most of the specimens were collected by Felix Speiser in 1912 from Malo, Pentecost and Espirtu Santo Islands, Vanuatu. The exact dates of these specimens are not known
11. Loyalty Islands (LOY)	50	BAS-43; PAR-7	Crania are from Mare, Lifou, and Ouvea Island Groups, Loyalty Islands. The exact dates of these specimens are not known
12. New Caledonia (NCL)	50	BAS-34; PAR-16	Crania are from several coastal and inland locations on New Caledonia. The majority of these specimens were collected in the late nineteenth century. The exact dates of these specimens are not known
13. Santa Cruz Islands (SCR)	46	SAM-4; AMS-2; BAS-40	The crania in Basel were collected by Felix Speiser in 1912 (Speiser 1928). The exact dates of these specimens are not known
14. Solomon Islands (SOL)	49	DRE-3; BER-1; NMV-1; QMB-3; AMS-16; DAS-10; BAS-14; GOT-1	Crania are from New Georgia (5), Guadacanal (9), San Cristobal Island (7), and other locations in the Solomon Islands. The exact dates of these specimens are not known
15. New Britain (NBR)	50	CHA-20; DRE-30	The specimens from New Britain in Dresden were collected by A. Baessler in 1900 and those in Berlin were collected by R. Parkinson in 1911. The specimens were collected from trading posts near Rabul in the Gazelle Peninsula and most likely represent Tolai crania. The exact dates of these specimens are not known
16. New Ireland (NIR)	53	AMS-4; BER-2; BLU-6; DRE-18; GOT-15; QMB-1; SAM-6; TUB-1	Most of the crania in Dresden were collected by Pöhl in 1887–1888 from the northern end of the island; the specimens in Göttingen were collected during the Südsee Expedition in 1908. The exact dates of these specimens are not known
17. Admiralty Islands (ADR)	50	DRE-20; GOT-9; CHA-6; TUB-15	Specimens from Hermit, Kaniet, and Manus Islands of the Admiralty Islands. The exact dates of these specimens are not known
New Guinea			
18. Sepik R. (SEP)	50	DRE-33; GOT-10; TUB-7	The specimens in Dresden were collected by Otto Schlaginhaufen in 1909 from various locations along the Sepik River, Papua New Guinea. The exact dates of these specimens are not known
19. Biak Island (BIK)	48	DRE-48	Most (45) of the specimens were collected by A.B.. Meyer in 1873 on Biak Island (Mysore), Geelvink Bay, Irian Jaya. The exact dates of these specimens are not known

(continued)

Biological Distance in Bioarchaeology and Human Osteology, Table 1 (continued)

Sample (abbrev.)	No. of crania	Location[a] and number of crania	Remarks
20. Purari Delta (PUR)	50	DRE-50	Decorated (engraved) skulls obtained by Gerard and Webster between 1900 and 1902 are from along the Purari River and Purari Delta regions, Papua New Guinea. The exact dates of these specimens are not known
Australia/Tasmania			
21. Murray R. (MRB)	50	AIA-39; DAM-11	Australian Aboriginal crania were collected by G.M. Black along the Murray River (Chowilla to Coobool) in New South Wales between 1929 and 1950. The exact dates of these specimens are not known
22. New South Wales (NSW)	62	AMS-21; DAS-41	Australian Aboriginal crania from the coastal locations in New South Wales. The exact dates of these specimens are not known
23. Queensland (QLD)	54	AMS-21; DAS-3; QMB-30	Australian Aboriginal crania from the southeastern and middle-eastern regions of Queensland. The exact dates of these specimens are not known
24. Northern Territory (NT)	50	AIA-4; AMS-3; MMS-1; NMV-38; QMB-1; SAM-3	Australian Aboriginal crania from Port Darwin (39) and Arnhemland (36) in the Northern Territory, Australia. The exact dates of these specimens are not known
25. Swanport, S.A. (SAS)	36	SAM-36	Australian Aboriginal crania representing the Tarildekald and Warki-Korowalde tribes in the lower Murray River basin. The specimens were collected by F.R. Zeitz in 1911 from an aboriginal cemetery located approximately 10 km southeast of the Murray Bridge in South Australia (Howells 1973:21). The exact dates of these specimens are not known
26. Western Australia (WA)	47	WAM-47	Australian Aboriginal crania from central (20), eastern (4), northern (14), and southern (9) regions of Western Australia. The exact dates of these specimens are not known
27. Tasmania (TAS)	26	THM-22; CHA-1; SAM-2; NMV-1	The crania represent Tasmanian Aborigines. The exact dates of these specimens are not known
Micronesia			
28. Guam (GUA)	46	BPB-42; PAR-4	Pre-Spanish Chamorro crania associated with *latte* structures collected in the 1920s by Hans Hornbostel along Tumon Beach, Tumon Bay, Guam. The majority of these specimens represent prehistoric (pre-1521) Chamorro
Island Southeast Asia			
29. Sumatra (SUM)	39	BER-1; BRE-1; DRE-5; LEP-4; PAR-3; ZUR-25	The specimens in Zürich are designated "Battak," specific locations within the island of Sumatra are not known. The

			exact dates of these specimens are not known
30. Java (JAV)	50	BER-1; BLU-8; CHA-9; DRE-1; LEP-24; PAR-7	Crania were collected from several different localities in Java. The exact dates of these specimens are not known
31. Borneo (BOR)	34	BER-2; BRE-2; DRE-6; FRE-4; LEP-8; PAR-12	A great many of the specimens are indicated as representing Dayak tribes, some have elaborate decorations. The exact dates of these specimens are not known
32. Sulawesi (SLW)	41	BAS-7; BER-10; DRE-4; FRE-7; LEP-5; PAR-8	An exact location is known for many of these specimens. The exact dates of these specimens are not known
33. Lesser Sunda Islands (LSN)	61	BAS-5; BER-15; BLU-2; CHA-1; DRE-24; LEP-1; PAR-6; ZUR-7	Crania from Bali (13), Flores (9), Sumba (1), Lomblem (2), Alor (2), Timor (11), Wetar (2), Leti (4), Barbar (1), Tanimbar (13), Kai (2), and Aru (1) Islands of the Lesser Sunda Islands. The exact dates of these specimens are not known
34. Southern Moluccas Islands (SML)	65	FRE-48; DRE-17	Crania are from Seram (48) and Buru (17) Islands of the Southern Molucca Islands. The exact dates of these specimens are not known
35. Sulu (SUL)	38	LEP-1; PAR-37	The specimens in Paris were collected by Montano-Rey circa 1900. The exact dates of these specimens are not known
36. Philippines (PHL)	28	BER-9; DRE-19	Most specimens are from Luzon Island. The exact dates of these specimens are not known
Mainland Southeast Asia			
37. Vietnam (VTN)	49	HCM-49	Near modern crania from Hanoi (Van Dien Cemetery) and Ho Chi Minh City
38. Bachuc Village, (BAC)	51	BAC-51	Victims of the 1978 Khmer Rouge massacre in Bachuc Village in western Angiang Province, Vietnam
39. Cambodia and Laos (CML)	40	PAR-40	A combined sample of crania from various locations in Cambodia and Laos collected between 1877 and 1920. The exact dates of these specimens are not known
40. Thailand (THI)	50	SIR-50	Most of the specimens represent dissecting room cases from Bangkok
41. Burma (BUR)	16	ZUR-16	The crania in Zürich are from a series (Cat. Nos. 93–125) of skulls collected in Mandalay, Myanmar (Burma), described in a catalogue dated circa 1900. The exact dates of these specimens are not known

Japan			
42. Kanto (KAN)	50	CHB-50	A dissecting room population of modern Japanese from the Kanto District of eastern Honshu. The majority of the individuals were born during the Meiji period (1868–1911) and died well before 1940
43. Tohoku (TOH)	53	SEN-53	Dissecting room specimens of modern Japanese from the Tohoku District in northern Honshu Island
44. Kyushu (KYU)	51	KYU-51	Modern Japanese, which derive mostly from Fukuoka Prefecture in Kyushu Island. Other specimens are from Yamaguchi, Saga, Nagasaki, and adjoining prefectures
45. Ainu (AIN)	50	SAP-18; TKM-5; TKO-27	Modern to near modern skeletons collected by Koganei in 1888–1889 from abandoned Ainu cemeteries in Hokkaido
46. Ryukyu Islands (RYU)	60	KYO-18; KAN-21; RYU-8; KYU-5; TKO-8	Eighteen near modern crania are from Tokunoshima Island of the Amami Islands located north of the Okinawa Group in the central Ryukyu Islands; 21 specimens are from two different locations on Kume Island, an island located west of Okinawa Island: Yattchi (17) and Hiyajo (4); 21 specimens are from five separate islands in the Sakishima Group of the southern Ryukyu Islands: Hateruma Island (2); Miyako (4); Iriomote Island (2); Ishigaki Island (1), and Yonaguni Island (12)
China and Northeast Asia			
47. Shanghai (SHA)	50	SHA-50	The specimens are mostly from post-Qing (pre-1911) cemeteries in Shanghai
48. Nanjing (NAJ)	49	SHA-49	The series represents near modern crania exhumed from the modern city of Nanjing, Jiangsu Province, eastern China
49. Chengdu (CHD)	53	SHA-10; CHE-43	A majority of these specimens date to the Ch'en Dynasty (A.D. 1644–1911) and are from Chengdu, Sichuan Province in western China. Ten crania are from Leshan, Lizhong County, Sichuan Province
50. Hong Kong (HK)	50	HKU-50	Specimens represent individuals who died in Hong Kong between 1978 and 1979
51. Taiwan (TAI)	47	TPE-47	Modern Chinese living in Taiwan who trace their immediate origins to Fujian and Guangdong Provinces on the mainland of China

(continued)

Biological Distance in Bioarchaeology and Human Osteology, Table 1 (continued)

Sample (abbrev.)	No. of crania	Location[a] and number of crania	Remarks
52. Hainan Island (HAI)	47	TPE-47	Near modern Chinese whose ancestors began migrating from the Canton region of China to Hainan Island around 200 B.C. (Howells 1989:108). This material was excavated by Takeo Kanaseki in Haikou City on Hainan Island
53. Manchuria (MAN)	50	TKO-50	Many of the specimens are from northeastern China or the region formerly referred to as "Manchuria," which today includes Heilongjiang and Jilin Provinces and adjacent northern Korea. A great many of these specimens are identified as soldiers, or cavalrymen, who died in battle in the late nineteenth century A.D
54. Korea (KOR)	32	KYO-7; SEN-3, TKM-2; TKO-20	Specific locations in Korea are known for most of these near modern specimens
55. Mongolia (MOG)	50	SIM-50	The skulls are identified as coming from Ulaanbaatar (Urga), Mongolia and were purchased by A. Hrdlička in 1912
56. Atayal (ATY)	36	TPE-28; TKM-7; TKO-1	The Atayal are the second largest surviving Aboriginal tribe in Taiwan. The specimens are Atayal slain in the Wushe incident in 1930. The specimens were collected by Takeo Kanaseki in 1932

to specialized studies that examine the shape of individual bones of the cranium to identify which are more strongly correlated with neutral genetic expectation and thus better suited for use in reconstructing human population history and primate phylogeny (e.g., Harvati and Weaver 2006; Reyes-Centeno et al. 2015; Smith and von Cramon-Taubadel 2015). While some regions of the human cranium (e.g., temporal bone, neurocranium) have been shown to support the neutral model of evolution better than others (e.g., mandible, facial and occipital regions) all regions of the skull have similar heritability patterns making cranial measurements recorded in these regions equally informative phylogenetically (e.g., Martínez-Abadías et al. 2009).

Future Directions

There is now abundant evidence global patterns of cranial shape are the result of neutral microevolutionary processes. As such, cranial variation (metric and nonmetric) can be used as a proxy for genetic data for addressing questions of biological relationships and history of past populations. Future work in studies of biological distance is anticipated to build on previous work in evolutionary quantitative genetics and contribute to a broad array of evolutionary questions in bioarchaeology, human osteology, and physical/biological anthropology. Refinements in quantitative methods including Bayesian statistical modeling and new imaging technology will undoubtedly continue to shape future work in this field. The use of geometric morphometrics and Cartesian coordinates of cranial landmarks for analyzing size and shape will also likely become more common in the field. While the use of digitizing equipment for recording 3D coordinate data is expected to increase in future work, reliance on traditional landmark measurements made with hand-held calipers will persist as an attractive, convenient, and less costly alternative.

The multivariate statistical procedures associated with traditional morphometric analysis such as principal components analysis, discriminant (canonical) analysis, and Mahalanobis distance will continue to occupy an important role in future biodistance studies. The reliance on multivariate methods associated with biological distance studies, old and new, reinforces the need for students to be familiar with the mathematical and theoretical aspects of these quantitative methods.

Although the majority of studies in biodistance have focused on the crania, mandibles, and teeth, some researchers have recently turned their attention to the postcranial skeleton (e.g., Betti et al. 2013). As have been demonstrated for craniodental variation, bones of the postcranial skeleton also demonstrate neutral variation and have the potential to address questions regarding population history. Likewise, the analysis of aDNA and other geochemical data will attract future research in biological distance. Combining data from multiple sources (e.g., Ricaut et al. 2010) will likewise provide new opportunities for reconstructing evolutionary and population history.

As never before, access to computers, imagining technology, user-friendly software for conducting biological distance studies, and sharing of data and quantitative methods will guide and inspire future studies.

Given the current repatriation claims and issues surrounding the accessibility of skeletal remains, the creation of data banks, and the sharing of data worldwide will provide a wealth of information that is nonrenewal. Many of the skeletal series examined in biodistance studies just a few decades ago using traditional morphometrics (e.g., Polynesians and Australian Aboriginals) are no longer accessible to future researchers. Likewise, because of the absence of genomic data for much of human prehistory, morphological data remains a powerful, and perhaps the single, source of information for analyzing human evolutionary history (von Cramon-Taubadel et al. 2017).

An Example of Biological Distance Analysis

In this example, two multivariate statistical procedures, stepwise discriminant function (canonical) analysis and Mahalanobis distance, are applied to 27 landmark cranial measurements recorded in 56 modern and near modern male cranial samples for understanding the population history of the Asia-Pacific region (Table 1, Fig. 1) (Pietrusewsky 2008b). Discussion of these results

Biological Distance in Bioarchaeology and Human Osteology, Fig. 1 Map showing the approximate locations of the 56 cranial samples used in the example. See Table 1 for a description of the samples (This figure, reproduced here courtesy of Etty Indriati of Gadjah Mada University, Yogyakarta, Indonesia, was originally published in Pietrusewsky (2008b))

is restricted to a canonical plot of group means and the dendrogram of Mahalanobis distances, with detailed discussion provided in Pietrusewsky (2008a).

Stepwise Discriminant Function Analysis

Three clusters emerge when the group means for the 56 group are plotted on the first two canonical variates (Fig. 2). One of these includes the cranial series from Australia, New Guinea, and geographical Melanesia. A second cluster includes the cranial series representing Polynesia and Guam. Cranial series from Mainland Southeast Asia and East Asia form a third major constellation. Of note, the cranial series from the Southern Moluccas, Admiralty Islands, and Lesser Sunda Islands occupy an intermediate position between the Polynesian and Australo-Melanesian cranial series.

Mahalanobis Generalized Distance

Applying the UPGMA clustering algorithm to Mahalanobis distances results in the dendrogram shown in Fig. 3. The primary division evident in this diagram places all the cranial series from Australia and Melanesia in one branch while the second includes the cranial series from Polynesia, Southeast Asia, and East Asia. Within these major divisions there is internal differentiation that generally mirrors geography. It is also worth noting that New Zealand Maori (Polynesia), Southern

Biological Distance in Bioarchaeology and Human Osteology, Fig. 2 Plot of 56 group means on the first two canonical variates resulting from the application of stepwise discriminant function analysis to 27 cranial measurements. Abbreviations of the cranial samples are explained in Table 1 (This figure, reproduced here courtesy of Etty Indriati of Gadjah Mada University, Yogyakarta, Indonesia, was originally published in Pietrusewsky (2008b))

Moluccas (island Southeast Asia), and the Admiralty Islands (Melanesia) cranial series form a cluster that ultimately links with the Australian-Melanesian branch in this diagram.

Australia/Melanesia Versus Southeast/East Asia and Remote Oceania

The presence of two major divisions demonstrated in these results supports archaeological, linguistic, and genetic models that the indigenous inhabitants of Australia, Tasmania, and geographical Melanesia share a common origin that is unrelated to that for the modern inhabitants of Southeast Asia and East Asia. The sharp separation between Polynesian and Australian-Melanesians series further reinforces archaeological and linguistic models. These models hypothesize an earlier colonization of Australia, New Guinea, and neighboring regions of Near Oceania and a much later colonization that led to the peopling of previously uninhabited Remote Oceania.

Southeast Asia and North/East Asia

These results further allow an examination of some of the current archaeological models advanced to explain the population history of East and Southeast Asia. The sharp contrast between East/North Asian and Southeast Asian cranial series does not support linguistic and archaeological models that argue that the

Biological Distance in Bioarchaeology and Human Osteology, Fig. 3 Dendrogram (or diagram of relationship) that results from applying UPGMA clustering algorithm to Mahalanobis distances using 27 cranial measurements recorded in 56 male groups (This figure, reproduced here courtesy of Etty Indriati of Gadjah Mada University, Yogyakarta, Indonesia, was originally published in Pietrusewsky (2008b))

indigenous inhabitants of Southeast Asia were replaced by immigrant groups of people of a more northern origin during Neolithic times.

Island Southeast Asia/Polynesian Homeland

These results also support an ancestral Polynesian homeland in East/Southeast Asia and not one within geographically adjacent Melanesia. The connection between New Zealand Maori (a Polynesian series) and the Southern Moluccas (Island Southeast Asia) cranial series supports a probable island Southeast Asian origin of the Polynesians, an association also demonstrated in previous analyses of genetic data.

Biometry in Zooarchaeology

David C. Orton
Institute of Archaeology, University College London, London, UK

Introduction

The measurement of bones is a routine aspect of zooarchaeological analysis. Requiring minimal equipment and relatively little experience, it nonetheless has the potential to contribute to many of the discipline's major recurring themes, including domestication, herd management, hunting strategies, and environmental change. Most analysts currently use the same standard set of measurements for mammals and birds – published by Angela von den Driesch in 1976 – allowing considerable scope for comparison between sites. A number of promising new statistical techniques such as mixture analysis have been applied to zooarchaeological biometry in recent years, but the development likely to have the biggest impact in the near future is the establishment of online repositories of measurement data, facilitating large-scale meta-analyses.

Definition

In the context of vertebrate zooarchaeology, biometry refers to the measurement of individual dimensions of hard tissues – primarily bone – and the calculation of simple indices. Common uses of measurements include species identification, sex determination, age estimation, assessment of domestication status, and tracing environmental changes.

Key Issues/Current Debates/Future Directions/Examples

Techniques and Standardization

For measurements to be useful, they must be repeatable and comparable. It is therefore necessary both to use equipment capable of producing reliable, accurate measurements and to ensure standardization between analysts in the exact dimensions to be measured.

The most common tools for zooarchaeological biometry are simple sliding calipers – typically digital, although many analysts prefer to use purely mechanical vernier or dial versions (Fig. 1). These have a main pair of (typically) straight arms allowing accurate external measurements up to 150 or 200 mm on moderate-sized bones, and usually also a smaller secondary pair of arms for simple internal measurements of foramina, diastemata, etc. Technical precision is typically 0.01 mm,

Biometry in Zooarchaeology, Fig. 1 Dial calipers being used to measure a cod vertebra. (Photo by author)

although this will rarely be achieved in practice due to observer error.

Larger calipers are also available, as are specialized versions with longer, narrower, and/or angled arms to permit measurement of larger or more awkwardly shaped bones. More commonly, however, such measurements are taken using a measuring box. Various designs exist but all feature a horizontal surface marked with a scale and two vertical blocks perpendicular to this: the first fixed at the zero point and the second capable of sliding along the scale in order to take a measurement on a bone held against the first. Measuring boxes are particularly useful when more than two measurement (i.e., contact) points are required in order to ensure the correct orientation for the dimension to be measured.

For very small bones, measurements can be taken through a microscope using a scaled graticule, or alternatively using digital image analysis. Finally, curved measurements are occasionally taken using a simple tape measure, for example for the outer length of a horn core or the basal circumference of an antler.

Inter-analyst comparability can only be achieved through the use of standard measurement definitions and clear indication of the standards employed in each case. Fortunately, a near-universal standard for terrestrial mammals and birds exists in Angela von den Driesch's *A Guide to the Measurement of Animal Bones from Archaeological Sites* (1976) – a comprehensive and fully illustrated list of measurements designed for the major taxa encountered on Holocene sites in Europe, with abbreviations allowing easy reference to specific measurements (e.g., "Bd" = distal breadth). These can generally also be applied for related taxa found in other parts of the world, but run into trouble for species that differ substantially in morphology, such as beavers or primates. Other measurement lists do exist, but are typically specialized sets to be used as supplements rather than alternatives to von den Driesch (e.g., additional sheep metapodial measurements in Davis 1996). The degree of morphological variation in fish makes definition of standard measurements more difficult, although some of those set out by Morales and Rosenlund (1979) are widely used. The existence of widely accepted standards allows for inter-site comparison and compilation of measurement databases such as ABMAP, hosted by the UK's Archaeology Data Service.

Log-Ratio Techniques

Isolated measurements may be useful if they can be compared with published datasets, but for many purposes a large sample of measurements from the same assemblage is required. Even in a large collection of bones, the number of measurable specimens of any given element and portion (e.g., distal humerus) may be very small, however, and it is often impossible to draw meaningful interpretations from measurements of individual elements.

The log standard index (LSI) or "log-ratio method" can be used to circumvent this problem by combining measurements from multiple elements. Originally developed by paleontologists, it was introduced to archaeology by Hans-Peter Uerpmann (1979) and Richard Meadow (1981). Each measurement in the assemblage is converted into an index representing its magnitude relative to the equivalent measurement on a "standard animal" – either a modern specimen, average values from a modern population, or a more or less complete archaeological skeleton. This is done by dividing the observed measurement by the standard measurement and then taking the base-10 logarithm: a measurement identical to that on the standard will result in an LSI value of

zero; a positive value indicates that the specimen is larger than the standard; and a negative value that it is smaller. The zero point is thus fairly arbitrary, but the LSI values can be used to assess the size distribution of specimens in an assemblage (Fig. 2).

One problem with this technique is that it assumes that *shape* does not vary systematically, that is, that the relative proportions of the standard animal are identical to those in the archaeological populations under study. Differences in relative proportions between the standard and the target population(s) have a blurring effect, increasing the dispersion of LSI values and making it harder to distinguish subgroups within the archaeological material. In theory this can be minimized by choosing an appropriate standard – ideally from as close as possible to the target assemblage in both time and space – but there is often little choice: studies of prehistoric cattle, for example, almost always use the "Ullerslev cow," a Danish Neolithic aurochs (Degerbøl and Fredskild 1970). Equally problematically, there may be systematic differences in proportions between the subgroups that one is trying to distinguish, for example males and females or wild and domestic specimens.

Of course, LSI values also provide a means to investigate shape changes, which may be of considerable interest in their own right. Given a large enough sample, LSI values may be plotted by element, with variation in mean values revealing differences in anatomical proportions compared to the standard (e.g., Davis 1996). Shape variation between individuals within a single population is also an issue, and Davis notes that while measurements in the same axis – that is, lengths *or* breadths *or* depths – tend to be highly correlated throughout the body, correlations are typically weaker *between* these categories.

In addition, pooling measurements from multiple elements is likely to lead to sample inflation: the same individual may be represented multiple times, increasing apparent sample size, violating assumptions of independence, and making "significant" results more likely in statistical tests. The LSI approach can be very powerful despite these problems, but wherever possible it should be used to supplement rather than replace analysis of size on an element-by-element basis.

Estimating Body Size/Weight

Bone measurements and derived indices are both useful for assessing relative size, but neither represents data of interest in and of themselves. It is often useful to estimate a more intuitively meaningful dimension from the measurements: whether discussing domestication-linked size reduction in the Neolithic or livestock improvements in the postmedieval period, for example, most readers will get a better idea of the changes involved if they are expressed in terms of withers height (i.e., height at the shoulder) rather than, say, metacarpal distal breadth or an index of size relative to one specific Danish aurochs. In some cases the role of derived size estimates may go further.

Biometry in Zooarchaeology, Fig. 2 Distribution of LSI value for goats (*Capra hircus*) from Çatalhöyük, West Mound, by reference to Uerpmann's (1979) standard animal. The *dotted line* marks the position of the standard (Author's own data)

For fish, the distribution of estimated total lengths may help to infer capture technology, while length is also a proxy for age (see below).

Modern reference data have been used to calculate linear regression equations for deriving major dimensions of numerous species from common bone measurements (e.g., May 1985 for horse withers height, Jones 1991 for gadid fish total lengths). In most cases these are simple bivariate linear regressions (Fig. 3), although it is also possible to build several measurements into a multiple regression. Such regression equations should ideally only be used for archaeological specimens which fall within the range of the reference data used in their construction (interpolation); application to specimens outside this range (extrapolation) may not be reliable. They should also ideally be based upon measurements taken in approximately the same axis as the dimension to be estimated, but this is not always practical. For example, withers height in livestock can be most reliably estimated from long bone *lengths*, but since long bones are typically fragmented in zooarchaeological assemblages, it may be necessary to use breadth or depth measurements instead, accepting a weaker correlation and hence larger error term (see Davis 1996).

For other purposes it may be the weight of an animal (or at least the weight of meat and fat) that is of most interest to the zooarchaeologist, but predicting live weight is more complicated than estimating height or length. Since weight is correlated with volume – a three-dimensional property – it should increase in a cube ratio relative to any given dimension, resulting in a non-linear regression curve. An additional complication is introduced by allometry: that is, size-correlated variation in anatomical proportions. In the context of zooarchaeology, the most important allometric effect is that between overall body size and the proportion of the body consisting of bone. Whereas weight depends on volume and hence increases in a cube ratio, the ability of bones to support this weight is (broadly speaking) a function of cross-sectional area – a two-dimensional property – and thus only increases in a square ratio. As animals get heavier, the size of their bones must therefore increase disproportionately in order to support their weight, further complicating the relationship between bone measurements and animal size.

Age and Sex Determination

Sex ratios may be of considerable interest to zooarchaeologists, shedding light on herd management or hunting techniques. Sex can most reliably be determined from qualitative differences such as pelvic or dental morphology, but many species also show marked quantitative sexual dimorphism, with males typically larger among mammals and the opposite occasionally true for birds. Unless dimorphism is extreme, however, distinguishing male and female specimens on the basis of measurements is necessarily

Biometry in Zooarchaeology, Fig. 3 Linear least-squares regression of first vertebra centrum height and total length in cod (*Gadus morhua*). The exact line depends on which variable is treated as dependent, neither being strictly correct. Length estimation is only reliable within the limits of the original dataset (Author's own data)

a probabilistic rather than absolute process: while the very largest and smallest specimens may be attributable to sex groups with some confidence, there is typically considerable overlap between male and female ranges. Even where it is impossible to determine the sex of individual bones, however, it may nonetheless be possible to estimate sex ratios within the assemblage as a whole, based on the shape of the observed distribution.

Since size distribution depends on a range of genetic and environmental factors, it must be treated as population specific; that is, one cannot rely on size ranges observed in modern populations to assign archaeological bones to sex groups. Rather, the zooarchaeologist must plot the available measurements and look for clustering empirically. In exceptional cases discrete size groups may emerge, but the best one can normally hope for is a continuous but bimodal distribution, which may be easier to interpret following smoothing with the kernel density estimate technique (Fig. 4). The degree to which sex groups can be determined within a population depends not only on the degree of dimorphism and the variation within each group but also on their relative abundance: where a small number of (larger) males are present alongside a much greater number of (smaller) females – as is typical in domestic herds – the male peak size may be obscured by the upper tail of the female distribution, perhaps visible only as a small "shoulder" towards the upper end of the overall distribution. A size distribution exhibiting positive skew may well indicate a small number of male specimens (or perhaps the inclusion of a few wild individuals – see below). Without independent information on the degree of dimorphism, it is very difficult to estimate relative frequency, although mixture analysis may help by fitting two (or more) normal distributions to the data as closely as possible (Monchot et al. 2005).

Where two groups emerge, these *may* represent males and females, although other factors such as the presence of wild and domestic populations (see below) may be responsible. If a few specimens of known sex (based on nonmetric characters) are included in the dataset, then they can be used to help test the assumption that observed size clusters represent sex groups. An additional complication among domestic animals is the possibility of castration, effectively introducing a third sex group. The exact effect of castration varies depending on the technique and timing (Moran and O'Connor 1994), but as a rule-of-thumb castrates tend to have relatively long bones due to delayed epiphyseal fusion (Davis 2000, see also Popkin et al. 2012). This effect is visible for metacarpal length versus breadth in a study of

Biometry in Zooarchaeology, Fig. 4 Histograms of metacarpal (**a**) and metatarsal (**b**) proximal breadths for cattle (*Bos taurus*) from Neolithic Gomolava, Serbia, with overlaid kernel density estimates. The main groups *probably* represent domestic females and males, while the upper outliers may be wild specimens. (After Orton 2008)

known-sex Shetland sheep, but there is too much overlap between rams, ewes, and wethers (castrated males) for reliable application to archaeological specimens (Davis 2000).

Metric data are generally of more limited use for determining age at death, although taxa with continuous ("indeterminate") growth, notably fish, are an exception. On a fine scale, the size of young fish may even be used to make inferences regarding season of catch. In the case of mammals, however, growth more or less ceases in most elements by the point of epiphyseal fusion, and wide variation in growth rate (see e.g., Popkin et al. 2012) means that measurement of immature specimens is of little use for estimating age.

Metric data may nonetheless contribute to understanding of kill-off patterns of domestic stock at an assemblage level. For obvious reasons, size distributions are normally constructed only from mature specimens – indeed, many zooarchaeologists do not even measure immature bones – and hence represent only the (sub)adult fraction of a population. Since males are typically slaughtered younger than females in domestic herds, size distributions will be heavily biased towards female specimens. Where measurements are available for unfused or otherwise immature specimens, however, these are likely to be biased in the other direction – towards males. Counterintuitively, the unfused bones may thus actually be larger on average than their mature counterparts, especially for late-fusing elements. Comparing the size distributions of fused and unfused specimens element by element, from earlier to later fusing, can thus help to identify the timing of the main male cull (Fig. 5), although once again the presence of castrates would complicate matters.

Finally, the use of tooth measurements to estimate age at death should be mentioned. Since tooth crowns wear down over time, particularly among herbivores, the remaining height of the crown can theoretically be used to estimate the length of time for which the tooth has been in use and by extension the age of the animal (e.g., Klein and Cruz-Uribe 1983). Several variants on this "crown-height" approach have been developed, with a range of different measuring protocols and varying complexity in the formulae used to estimate age, but

Biometry in Zooarchaeology, Fig. 5 Distribution of LSI values for distal metacarpals of sheep (*Ovis aries*) from Çatalhöyük West Mound, including both fused and unfused/fusing specimens. *Arrows* show mean values. The narrower range and smaller average size seen for mature specimens suggests that they are predominantly female and thus that most males were killed before fusion of the distal metacarpal (18–30 months according to Zeder 2006) (Author's own data)

all suffer from several drawbacks – most notably inability to account for variation in the height of the unworn crown (see Twiss 2008).

Domestication

One of the most hotly debated applications of zooarchaeological biometry is to the detection of domestication and the distinction of wild and domestic specimens within an assemblage. Most species saw a rapid reduction in both size and dimorphism following domestication, thought to be due to the relaxation of certain selection pressures that applied within wild populations (Zohary et al. 1998). Biometry is thus one of the main lines of evidence that has been used to document the process of animal domestication, alongside changing age and sex structures, pathologies, and artifactual data.

Changes in morphology must necessarily have lagged behind the changes in human-animal interaction that represent domestication per se, but the speed with which size reduction manifested is hard to establish. Tracing size declines in a population over time will only ever provide a terminus ante quem for domestication in this sense, although the question of when domestication can be said to have occurred is in any case as much a theoretical as a practical one. Ideally, biometry should be complemented by assessment of changes in age and sex profiles, the latter being likely slightly to predate reduction in size.

Of course, domestication is only one possible cause of size decline: intensive selective hunting can depress the size of available prey over time, for example, while environmental changes may result in shifts in size distribution among wild populations without any human intervention. A stronger case that size decline represents domestication can be made where other species with similar habitats can be shown not to have undergone the same changes over the same time span (e.g., Arbuckle and Makarewicz 2009).

Once a domestic population of a species has been established, hunting of wild individuals may nonetheless continue. Separating wild and domestic individuals within a zooarchaeological assemblage – or at least estimating their relative abundance – presents a challenge analogous to that of distinguishing sex groups, but with the added complication that both wild and domestic populations will include male and female groups. One cannot even assume that the offset between the sexes is the same in each population, since dimorphism is often much reduced in domestic herds (Zohary et al. 1998).

Where both wild and domestic populations of a dimorphic species are likely to be present in an assemblage, interpreting the size distribution can become quite complicated, with a trimodal distribution not uncommon (Figs. 4b; 6). Mixture analysis may again help to tease apart components within relatively large samples, but cannot entirely circumvent fundamental problems of equifinality: statistics may help to identify and quantify subgroups within a sample, but cannot reveal what they represent. Once again, the presence of a few known-sex specimens can help to choose between different interpretations of a bi- or trimodal size distribution (Fig. 7).

		Group 1	Group 2	Group 3
Bimodal	*a*	dom. ♀	dom. ♂	
	b	wild ♀	wild ♂	
	c	dom. ♀, ♂	wild ♀, ♂	
	d	dom. ♀, ♂, wild ♀	wild ♂	
Trimodal	*e*	dom. ♀	dom. ♂, wild ♀	wild ♂
	f	dom. ♀, ♂	wild ♀	wild ♂

Smaller ← → **Larger**

Biometry in Zooarchaeology, Fig. 6 Potential interpretations of observed bi- or trimodal size distributions for a dimorphic species with wild and domestic forms. Options *a* to *f* are not exhaustive but represent some of the more likely interpretations (excluding the possibly of castrates)

Biometry in Zooarchaeology, Fig. 7 Lower third molar measurements from pigs (*Sus scrofa*) at Neolithic Gomolava, Serbia, with sex highlighted where known (from canine morphology). The two clusters could represent either male and female or wild and domestic (options *a*/*b* or *c*, respectively, in Fig. 6), but the presence of both sexes in the upper cluster strongly supports the latter. (After Orton 2008)

Biomolecular Archaeology: Definition

E. Christian Wells
Department of Anthropology, University of South Florida, Tampa, FL, USA

Brief Definition of the Topic

Biomolecular archaeology, a subfield of archaeometry, is the study of ancient molecules (especially nucleic acids, proteins, lipids, and carbohydrates) produced by past living organisms, most often applied to identifying organic residues from archaeological sites and objects, recovering DNA from human tissues and skeletal remains, and studying genetic parameters of plant and animal domestication. Research seeks to understand the processes that result in the preservation of biomolecules as well as the ways in which biomolecules can be used to reconstruct paleoenvironments and, more broadly, assess human biological and cultural evolution. Analytical techniques derive principally from chemistry (e.g., mass spectroscopy, isotope analysis), evolutionary biology (e.g., PCR), and proteomics (e.g., immunoassay, decoding genomes), among other sources. Important syntheses of the field and applications are provided by Hedges and Sykes (1992), Evershed (2008), and Brown and Brown (2013). Analytical methods and research examples are covered in recent texts by Gaines et al. (2008) and Brown and Brown (2011). Since 2004, there has been a biennial International Symposium on Biomolecular Archaeology hosted at various institutions around the world.

Bird, Junius

Fabiana María Martin
Instituto de la Patagonia, centro de Estudios del Hombre Austral, Universidad de Magallanes, Punta Arenas, Chile

Basic Biographical Information

Junius Bird was born in 1907 in Rye, New York, and from an early age was attracted to both archaeology and maritime adventures. As a young man, he participated in several expeditions to the Arctic Ocean, starting in 1927 when he joined Bartlett's Arctic expedition. He entered the field of archaeology without academic training, but his field knowledge and capacity led him to a post as a field assistant at the American Museum of Natural History in New York. From that base, he participated in numerous archaeological expeditions to different regions of the Americas, especially in Canada, the United States, and Central America, particularly in Panama, Peru, and Chile. In time, he became the museum's head curator of South American archaeology. In 1932, he visited Navarino Island, north of Cape Horn, where he spent several months surveying the entire north shore, excavating a shell midden at Puerto Pescado. It was there that he began the systematic application of stratigraphic principles to archaeological research, and he became convinced of the possibilities for archaeological discoveries in Patagonia and Tierra del Fuego.

In 1934, Bird and his wife, Peggy, departed to South Chile for a period of two and half years to survey its channels. There, they explored the maze of southwestern channels by sailing for six months in a 19-foot sailboat. This was a dangerous trip through a sparsely populated and almost unknown area characterized by heavy rainfall and continuous storms. The trip was successful due to the discovery of many sites, mostly shell middens, and opened up a whole new region for archaeological research (Martinic 1984). Following this trip, Bird began the archaeological exploration of the Patagonian steppes, discovering important sites in Cañadón Leona and Pali Aike.

Major Accomplishments

Bird was the definitive fieldman, with the capacity to produce good results with minimal equipment. He was famous for traveling the dirt roads of the Patagonian steppes in a Model T Ford. He constructed his own dump sifters, perfecting them over time. During his coastal trips, he discovered shell middens in many places, some of which he placed chronologically by making meticulous geological observations. It must also be noted that Bird made several relevant and astute taphonomic observations about the process of accumulation of bones in caves. He was a keen observer of what we now call formation processes.

As a result of these trips, particularly those to South Chile, Bird discovered some of the earliest evidence of the presence of humans in the Americas. He discovered in the Pali Aike Volcanic Field some of the sites that would become classic references when discussing human interaction with extinct Pleistocene fauna in the Americas. Both at Pali Aike and the Fell Caves, he was able to recover ground sloth (*Mylodon darwinii*) and horse (*Hippidion saldiasi*) bones as well as abundant camelid (*Lama* sp.) bones associated with hearths and lithic and bone artifacts. The lithics discovered include the world-famous "fishtail" projectile points, a marker of the earliest Americans.

Junius Bird's interest in Patagonia continued until the end of his life. He returned several times to collect samples for specific analyses. For example, he was among the first archaeologists to use Willard Libby's discovery of the radiocarbon dating technique to date human occupations, and using this technique, he was able to place human arrival in southern South America at around 11,000 years BP. This is more or less the oldest age that can be defended today, some sixty years later, for the first human peopling. He also returned to excavate new sites. His last field work in Patagonia took place in 1980, when he excavated the Tom Gould site, a rich open-air site in Pali Aike (Massone 1989–1990).

Bird's publications constitute classic references not only for the archaeology of the early peopling of America (i.e., Bird 1938, 1946, 1988) but also for the history of human occupation at different places along the Pacific coasts of South America.

One important result of Bird's studies is that he constructed a cultural and chronological scheme for Patagonia that is still in use today (Martin et al. 2011). However, it must be emphasized that he never restricted the scope of his interest to Patagonia, and his excavations in North Chile and North Peru rank among the most important archaeological antecedents for modern archaeology in South America.

After a long and productive life, Junius Bird died in New York in 1982. The people who knew him noted his enthusiasm and skills in the field, as well as the clarity of his research goals. Junius Bird's great contributions to our present understanding of Patagonian archaeology cannot be exaggerated.

Black Death: Cultures in Crisis

Sacha Kacki
CNRS, PACEA, Université de Bordeaux, Pessac, France
Department of Archaeology, Durham University, Durham, UK

Introduction

Between the years 1346 and 1353 CE, a terrible disease swept across Europe, the Middle East, and North Africa, bringing death and desolation in its wake. This widespread epidemic, now known as the "Black Death", caused dramatic losses, surpassing those of any large-scale disaster recorded before. In Europe, the disease killed an estimated 30–60% of the population over a 5-year period (Benedictow 2004). Its impact elsewhere in the Old World is not as well-known, but historical evidence suggests massive depopulation as well (Borsch 2014). By causing such a large demographic collapse, the Black Death initiated or enhanced major social, economic, and political

changes throughout Western Eurasia and Northern Africa (Horrox 1994; Borsch 2014). It also constituted the starting point of a period of high mortality, marked by recurrent outbreaks of the disease over the next four centuries (Biraben 1975). Due to its many effects on society and culture, the Black Death is generally considered as one of the most significant events of the late medieval world and as a turning point in European history.

Definition

The Black Death was the first and most devastating outbreak of the second plague pandemic, a major series of epidemics that took place between the mid-fourteenth and the late eighteenth centuries CE. It is noteworthy that the term is a recent coinage that seemingly came into use not before the eighteenth century. In medieval sources, the epidemic was referred to using various and more general terms, including *epidemia*, pestilence, great death, and great mortality. It is commonly, but inaccurately, said that the term "Black Death" originated in the petechial hemorrhages (dark spots of blood under the skin) that sometimes accompanied the disease. The name more likely comes from a mistranslation of the Latin expression *atra mors*, where *atra* may mean either "black" or "terrible" (Benedictow 2004).

The second plague pandemic, as well as the Justinian plague (i.e., the first plague pandemic of the sixth to eighth centuries CE), has long been considered to have been caused by the bacterium *Yersinia pestis*, i.e., the same etiological agent responsible for modern plague outbreaks. This gram-negative coccobacillus, which evolved from the closely related enterobacterium *Y. pseudotuberculosis*, is one of the most virulent pathogens known to humans. Humans, however, are only accidental hosts for the bacterium. Plague is primarily a disease of rodents (such as rats, marmots, and squirrels), which constitute permanent reservoirs for the bacterium. In modern-day epidemics, humans are most commonly infected by inoculation with the bacterium via the bites of fleas that had previously fed on infected animals (in particular, the rat flea *Xenopsylla cheopis*).

Plague can present in different clinical forms depending on the route of the infection. By far the most common is bubonic plague, in which *Y. pestis* bacteria spread to lymph nodes, where they multiply and give rise to enlarged purulent abscesses (the so-called buboes). Other symptoms of the disease include headaches, aching joints, nausea, and vomiting. Without antibiotic treatment, about 40–70% of those affected with the disease die in about a week after appearance of the first symptoms due to cardiotoxins released from the buboes. Although rare occurrences in modern outbreaks, the bacteria can also enter the blood stream or migrate to the lungs, leading to highly fatal forms of the disease (septicemic plague and pneumonic plague, respectively). Pneumonic plague is the only clinical form that has the ability to spread directly between humans, through inhalation of respiratory droplets from an infected individual.

A number of scholars have raised questions about whether or not the Black Death actually was an epidemic of plague, pointing to differences in mortality rate and epidemiology between the medieval epidemic and late nineteenth/early twentieth plague outbreaks. In recent years, however, ancient DNA (aDNA) analysis of skeletal remains of plague victims provided conclusive evidence that *Y. pestis* was the causative agent of the second pandemic, including the Black Death (Haensch et al. 2010; Spyrou et al. 2019). aDNA studies also confirmed its involvement in the first plague pandemic (Feldman et al. 2016) and revealed that the bacteria already caused human infections as early as 5,000 years ago, while acquiring its ability for flea-borne transmission only during the Bronze Age (Spyrou et al. 2018). That *Y. pestis* was responsible for the Black Death is thus no longer a subject of controversy. Nevertheless, the reasons why the disease spread so fast and was so deadly in the medieval period are still to be elucidated.

Historical Background

Origin and Spread

The exact geographic origin of the Black Death, as well as the route the disease followed prior to its entry into Europe, remains uncertain. Most historians agree that the epidemic began somewhere in Asia and traveled westward during the early fourteenth century, either via Silk Road merchants or via the Mongol army. An East Asia origin has been proposed based on genetic data, as modern *Y. pestis* strains that are directly ancestral to the lineage diversification that gave rise to the strains involved in the second plague pandemic have been identified in China near historical trade routes (Cui et al. 2013).

The first clear records of the Black Death place the disease in the Lower Volga and Black Sea regions in the mid-1340s. According to chronicler accounts, plague had been transferred to Europe from the Black Sea port of Caffa (modern Feodosia, Crimea), at that time a Genoese trading station. In 1345–1346, the Italian colony was besieged by troops of the Golden Horde (the Mongols who ruled over the steppes of southern Russia) who, after plague erupted in their ranks, allegedly infected the inhabitants by catapulting the bodies of victims over the city walls (Horrox 1994). Whether or not this story is accurate, the disease spread in the city, and the Genoese were forced to flee. Some ships managed to leave Caffa in the fall of 1347, passing through Constantinople (modern Istanbul) and stopping in Messina (Sicily) before returning to Genoa. By the end of the year, the disease raged in Constantinople, Greece, and most of the Mediterranean islands (Crete, Sicily, Sardinia) and reached Marseilles in France and Alexandria in Egypt. The epidemic then disseminated rapidly both northward across Western Europe and westward across North Africa. Within a year, plague spread across France, Italy, and Spain. By the end of 1349, it had colonized most of the British Isles and Germany. Continuing northeastward, plague infected Eastern Europe and the Low Countries in the next year, and reached the city of Moscow in 1352. In less than 5 years, the disease had spread everywhere, from Spain to the Urals and from Greece to Norway, sparing only a few regions.

After the Black Death, plague continued to rage in Europe and Northern Africa, as evidenced by the hundreds of recorded outbreaks for which it seems to have been responsible between 1353 and the late eighteenth century (Biraben 1975). While some studies have suggested that these later plague epidemics were caused by climate-driven reintroductions of the bacterium from reservoirs in Asia, genetic evidence currently favors its persistence in Europe in local rodent reservoirs (Spyrou et al. 2019).

Consequences of the Black Death

Although an accurate death toll is impossible to calculate in the absence of reliable demographic statistics, it is estimated that the Black Death killed one-third to over one-half of the European population. Faced with a disaster of such an unprecedented magnitude, many contemporaries of the epidemic considered that the disease was a punishment from God for the sinfulness of mankind (Horrox 1994). This belief led, at first, to increased demonstrations of popular piety in an attempt to appease God's wrath. Public processions and masses were organized in many communities across Europe, and the Church encouraged the faithful to various forms of penance, including devotion to saints, pilgrimage, and monetary offerings. In some parts of Europe, the Flagellants gained a large popularity, the members of this extreme penitential movement traveling from town to town and making bodily penance by scourging themselves in public. The ineffectiveness of any of these actions to stop the spread of the disease rapidly gave rise to other opinions and conspiracy myths, notably allegations that the plague had been caused by human agency (Horrox 1994). Accusations were leveled against virtually anyone viewed as an outsider, including foreigners, travelers, the poor, and lepers. But more than any others, the Jews were the most frequent scapegoats. Accused of causing the epidemic by poisoning wells and rivers, many Jews were harassed and expelled from communities, and thousands were massacred, particularly in Spain, southern France, and the Rhine valley.

At a loss to explain the cause of the Black Death, many people tried to escape the disease by fleeing from infected areas, abandoning their homes, villages, and cities. Others, who could not afford to flee, cloistered themselves away and avoided public venues for fear that the disease spread from person to person. The popular belief in contagion also led some people to refuse to care for the sick and to bury the dead, and these duties were often left in hands of the more charitable and the poor (Fig. 1). As a result of the excessive number of corpses accumulating, burial sometimes could no longer be carried out individually, and victims were buried anonymously in mass graves. In some cities, existing graveyards became saturated and mass burial grounds were established, as in London where two such cemeteries were opened at East and West Smithfield.

Beyond its immediate effects, the Black Death also had profound long-term consequences. The most obvious was a drastic population decline, which was long-lasting due to repeated outbreaks of plague in the following decades and centuries. Although not matching the mortality levels of the Black Death, these later epidemics resulted in demographic stagnation in Europe, and populations did not return to their pre-Black Death levels until the sixteenth century in France, Italy, and Spain, and not until the eighteenth century in England (Pamuk 2007). The massive depopulation caused a shortage of labor that ultimately resulted in an improvement in the standards of living for the working classes. While before the Black Death peasants had little latitude to negotiate wages, labor obligations, or rents, those who survived the epidemic were now able to bargain for more favorable terms of employment as the supply of land generally exceeded demand. Similarly, craftsmen and paid laborers were able to charge higher prices for their services and goods. It resulted in a dramatic increase of real wages for both peasants and urban workers, while prices for food and housing generally went down (Horrox 1994; Benedictow 2004). Governments quickly attempted to curtail these economic shifts by adopting laws to limit wages and the movement of workers. These laws were only

Black Death: Cultures in Crisis, Fig. 1 People burying victims of the Black Death in Tournai, Belgium. Miniature by Pierart dou Tielt illustrating the *Tractatus quartus* by Gilles Li Muisis (ms. 13,076–13,077 fol. 24v., Tournai, c. 1353)

partially successful, and they motivated social uprisings such as the 1381 Peasants' Revolt in England.

Overall, the Black Death resulted in a redistribution of wealth, a reduction in social inequalities, and an improvement in housing and diet for people of all social strata. It likely contributed to the end of the feudal system and diversification of the European economic culture (Horrox 1994). By reducing population size, the epidemic indeed offered the opportunity to use some lands for other purpose than raising food crops, which led to a progressive shift from grain farming to animal husbandry. Similarly, some of the grain mills could be repurposed and were used to saw wood, to full cloth, or to operate bellows. The high cost of labor also encouraged the development of laborsaving technologies and the rationalization of working procedures, with the aim of increasing productivity.

The Black Death and later plague outbreaks also had long-lasting cultural and psychological effects on the European population, which are particularly apparent in art and literature. The dreadful trauma of these epidemics instilled an atmosphere of gloom and doom in society, leading writers and painters to move away from optimistic themes and to turn to an obsession with the plague and death. The *Danse Macabre* ("Dance of Death"), in particular, became an increasingly common theme in art through the course of the fifteenth century, which emphasizes the fragility of life and unforeseeable nature of death.

Key Issues/Current Debates

A long-standing topic of interest to historians, the Black Death has also gradually become the focus of active archaeological research in recent decades. Various approaches and methods from a wide range of subdisciplines have been used to attempt to detect physical evidence of the epidemic in the archaeological record, with the ultimate objective to confirm or refute claims about the effects of plague inferred from documentary sources. Possible archaeological evidence of the mass mortality caused by the Black Death and its social outcomes include mass graves, the abandonment or reduction in size of settlements, aborted building projects, and a decrease in goods production. To establish causal relationships between the epidemic and such archaeological findings is challenging as any one of them could potentially result from causes other than plague. In addition, some of these features are difficult to identify, and none is as common as could be expected, suggesting a great diversity of human responses to the Black Death and necessitating the use of multiple lines of evidence to reach informed interpretations.

Archaeological Evidence of Population Decline and Economic Disruption

Landscape archaeology was the first branch of archaeology to provide a significant contribution to the scholarly study of the Black Death, through studies on deserted medieval villages (Fig. 2), which boomed in the 1950s, notably in England. Before these investigations, many deserted villages were thought to have been abandoned due to the depopulation caused by the Black Death and their subsequent failure to recover. Archaeological excavation and chronological characterization of a number of such settlements dismissed this hypothesis, showing that most investigated villages were not abandoned until the fifteenth century or later, when fields used for crops were transformed into pastures (Beresford and Hurst 1971). These results led to changed perceptions of the impact of the Black Death on rural communities and suggested that most of them were resilient when faced with the epidemic. This does not mean, however, that villages as well as cities were not severely affected by population losses. In recent years, the mass mortality associated with the Black Death was persuasively demonstrated through a program of intensive test pitting carried out on over 50 settlements from eastern England (Lewis 2016). Using frequency and spatial distributions of pottery sherds as a proxy of human presence, this study revealed population decline at all sites and frequent contraction of the settlements in the 150-year period that followed the epidemic when compared with the 150-year period that preceded it. While variable from one

Black Death: Cultures in Crisis, Fig. 2 Example of a deserted medieval village at Hound Tor in Devon, England. (Photo from Google Earth)

site to another, the decline in the number of pottery sherds was on average 45% across the region, with severe reductions recorded in both small villages and towns, as well as in both nucleated and more dispersed settlements, thus suggesting widespread depopulation.

The economic consequences of the Black Death are difficult to evaluate based on archaeological features and artifacts alone. However, archaeological and earth sciences may provide indirect evidence of some of them. For example, analysis of ice core samples from an Alpine glacier revealed a dramatic drop in atmospheric lead levels concomitant with the Black Death, suggesting a sudden cessation of metallurgical production during the epidemic (More et al. 2017). Paleoecological reconstructions of vegetation in northwestern Europe from pollen diagrams show significant changes in land use during the late medieval period, some of which may have been initiated or hastened by the Black Death. While the identified decline in cereal production probably began in Britain and France before the epidemic, the increase in forest cover in the second half of the fourteenth century may be the direct consequence of abandonment of farmlands and grazing lands due to a shortage of farmers (Yeloff and Van Geel 2007). Similarly, a large-scale analysis of dendrochronologically dated European wooden constructions and comparison with annual records of plague epidemics revealed a correlation between building activity and the number of plague outbreaks, with the greatest decrease in construction occurring in the years following the larger epidemics (Charpentier Ljungqvist et al. 2018).

Burial Evidence of Mass Mortality

It is a common assumption that, due to brutal decimation of communities caused by the mid-fourteenth plague outbreak, burial traditions were strongly disrupted, and many victims were buried in mass graves. Multiple burials, therefore, are generally considered as the most reliable physical evidence on which to infer the possible relationship of a burial ground with the Black Death.

It is noteworthy, however, that not all victims of the epidemic were buried in mass graves and that a large, albeit unquantifiable proportion of them were interred in individual graves that are generally indistinguishable from those used under conditions of normal mortality. This means, in turn, that certain sites of interment for plague victims may contain mainly, if not uniquely, individual graves, making them much more difficult to identify in the archaeological record.

Multiple burials are easily detectable through archaeological excavation (Fig. 3), as far as appropriate excavation and recording methods are used, in particular careful observations of the spatial arrangement of the skeletal elements to distinguish them from collective graves (i.e., places where several bodies were deposited successively over time). It is challenging, however, to establish the relationship of a mass grave with the Black Death, as plague does not produce

Black Death: Cultures in Crisis, Fig. 3 Multiple burials from Black Death sites at Toulouse (**a**) and Saint-Laurent-de-la-Cabrerisse (**b**) and from late sixteenth century plague cemeteries at Les Fédons (**c**) and Dendermonde (**d**). (Images courtesy of M. Gourvennec (Archeodunum), A. Gaillard (Acter Archéologie), D. Castex (CNRS – PACEA), and E. Goudie Falckenbach (Antea Group), respectively)

lesions on bones and thus cannot be diagnosed based on visual, macroscopic, or radiological examination of skeletal remains. Both historic documents and dating information may be instructive, but they are rarely precise enough to link a specific burial site with a specific mass mortality event. Analysis of the age distribution of the skeletal assemblage may also be informative, as plague was shown to have a specific demographic signature, which can be recognized across space and time (Castex and Kacki 2016). A secure diagnosis of plague, however, can be achieved only through biomolecular analysis of the victim remains. Over the past two decades, both paleogenetic approaches (e.g., Haensch et al. 2010) and paleoimmunological techniques (e.g., Kacki et al. 2011) have successfully been applied for the retrospective diagnosis of the disease. In recent years, newly introduced paleogenomic methods have produced groundbreaking results, permitting not only the detection of plague-specific aDNA sequences but also the reconstruction of the whole genome of ancient strains of *Y. pestis*, thus opening the possibility of tracking genetic changes in the bacterium over centuries. These studies have produced compelling evidence for low genetic diversity and absence of mutations that account for increased virulence in the *Y. pestis* strains associated with the Black Death (Spyrou et al. 2019).

So far, archaeological excavations and subsequent molecular analyses of skeletal remains have made it possible to identify some 50 European burial sites related, wholly or in part, to the second plague pandemic, most of them in England, France, Germany, and Italy (Fig. 4). Among them, 16 can be confidently attributed to the Black Death, while the others are related to later plague outbreaks up to the eighteenth century. Burial patterns observed at these sites reveal a great diversity in the way the communities responded behaviorally to plague mortality, and progressive changes in funerary practices over the

Black Death: Cultures in Crisis, Fig. 4 Location map of European archaeological sites from which the graves of second pandemic (fourteenth to eighteenth century CE) plague victims have been excavated

course of the second pandemic (Kacki et al. 2019). They suggest that during the Black Death people generally attempted to adhere closely to traditional burial customs. With the exception of a few burial grounds created especially for plague victims, such as the East Smithfield cemetery in London, most of the victims were buried in graveyards that were previously in use before the epidemic. Contrary to frequent assumptions, the deceased, although sometimes put in mass graves, were treated with great care, most of them being placed in the graves in an extended supine position, oriented east to west, with their heads to the west as in most Christian burials. During later plague outbreaks, burial practices underwent noticeable changes. Most of the victims were then buried in dedicated cemeteries, and their skeletons show more heterogeneous orientations and more random positions (e.g., prone positions, head-to-foot arrangements). Archaeological evidence also reveals that from the seventeenth century onward, most bodies were covered in lime, while this practice was unusual in earlier centuries.

Bioarchaeological Research on the Black Death

Skeletal remains derived from plague pits, which constitute the only direct evidence of whom the victims were, have become the focus of increasing interest in bioarchaeology over the past 20 years. Their analysis may provide insight into the patterns of mortality associated with the disease (as inferred from the demographic composition of plague assemblages) and on the variations in individual risk of death with respect to various biological factors (e.g., pre-existing health status, dietary status). By this means, bioarchaeology contributes to revealing the epidemiological patterns of plague in past societies and to evaluating how its impact differed depending on environmental, socioeconomic, and/or behavioral factors.

A large part of the bioarchaeological research on the Black Death has centered on the 1348/1349 East Smithfield cemetery in London. The multiple paleodemographic studies conducted on this site resulted in mixed results, some concluding that the epidemic affected all age groups equally (Gowland and Chamberlain 2005), while others highlighted similarities between this skeletal sample and attritional assemblages, which were interpreted as an evidence that the Black Death killed discriminately with respect to age (DeWitte 2010). The major limitation with these studies is that all relied on the examination of a single site, making their conclusions difficult to generalize to explain epidemiological patterns of plague. In recent years, comparative analysis of various European skeletal assemblages associated with the Black Death and later plague outbreaks have produced results in favor of the non-selective nature of the disease, by revealing a similar pattern of mortality across these various sites, which fits with the expected age composition of a living population (Castex and Kacki 2016; Kacki 2017). In neither of these studies, sex was shown to strongly affect the risk of death.

In addition, a few studies have used paleopathological data to evaluate whether those individuals in poor health were more likely to die during the Black Death. Specifically, DeWitte's pioneering analysis of the East Smithfield assemblage has shown that people who developed skeletal stress markers earlier in life were more likely to die during the Black Death than those without lesions, thus supporting the hypothesis that *Y. pestis* infection was selective with respect to pre-existing health (DeWitte and Wood 2008). This conclusion is challenged, however, by the results of the study of four other plague burial grounds, which failed to demonstrate any significant difference in the risk of dying from the disease between individuals with and without skeletal lesions (Kacki 2017). The reason why these two studies differ in their conclusions is still to be elucidated, but this might lie either in temporal and/or spatial variation in the patterns of selectivity of plague or in methodological differences resulting in biased interpretations. In any case, further investigation on other large plague assemblages and consideration of other proxies for health (e.g., skeletal growth patterns, dietary status) will be needed to more confidently assess the influence of pre-existing health on the risk of dying from plague.

International Perspectives

Much of the archaeological research on the Black Death has thus far focused on the Western Europe. England, in particular, has been central to the work of many scholars, whether they are interested in the social consequences of the plague-driven depopulation or in the mortality patterns associated with the disease. Bioarchaeological research on plague victims from the British Isles, for a long time restricted to studies on the East Smithfield cemetery, has been expanded in recent years to other burial assemblages, giving rise to interdisciplinary programs such as the *After the Plague* project (http://www.aftertheplague.com/). There is also a long tradition of research on past epidemics in France, notably with respect to the study of plague pits and the skeletons they contain. Although much work was done on burial grounds linked with early modern plague outbreaks (e.g., the 1720 Great Plague of Marseille), recent discoveries and investigations provided more data on the Black Death, which is now at the center of various scientific projects, such as the French National Research Agency's MORTUI research program.

Until recently, little attention has been paid to the possible physical evidence of the Black Death in other parts of the Old World. Such evidence are, for now, virtually absent from the Asian archaeological record, and they are limited in Eastern Europe to the identification of *Y. pestis* aDNA in a few fourteenth-century skeletons from the Volga region of Russia (Spyrou et al. 2019). A few studies have lately tackled the question of plague outbreaks in Africa based on the examination of archaeological evidence suggestive of population decline. These studies revealed changes in settlement patterns in late fourteenth-century sub-Saharan Africa, a result considered as strongly supporting the still-debated hypothesis that the Black Death reached this region of the continent (Chouin 2018). However, other evidence for the disease, such as that for increased mortality and/or molecular detection of the bacterium in skeletal remains, is still lacking. Acquiring such evidence will be far more challenging than it has been for Europe, considering both the scarcity of mass graves in the archaeological record of medieval Africa and the generally poor preservation of aDNA in warm, tropical areas.

Future Directions

Over the past decades, archaeological research has contributed to improve perceptions of the demographic impact of the Black Death and its consequences on medieval societies. However, the research conducted so far is clearly biased toward Western Europe. To draw a broader picture of the epidemic and its aftereffects will require future research that transcends European borders and produces more data for Asia and Africa. In this regard, analysis of settlement patterns in various parts of these continents will be important to assess possible changes in population density during the fourteenth century. Definite inferences about the geographical spread of the disease, however, will require molecular detection of *Y. pestis* aDNA from skeletal remains exhumed from these regions. Careful archaeological excavations focused on identifying deviant burial practices, along with improved paleomicrobiological techniques, will undoubtedly increase the chances of gaining such evidence in the future.

A better assessment of the depopulation caused by the Black Death, both in Europe and beyond, could probably be achieved through the generalization of quantitative studies such as those conducted on pottery sherds in England (Lewis 2016). Be it by a test pit approach or through the analysis of archaeological finds recovered from extensive excavations, comparison of the amount of material remains from the pre- and post-Black Death periods will likely permit a more subtle quantification of the diverse impact of the epidemic in various localities and regions. In addition to ceramic remains, this approach would benefit from including other types of archaeological material, such as small metal finds or faunal remains related to animal consumption.

In order to gain a more globalized understanding of the origins and impact of the Black Death, it would be desirable that future research include more environmental studies. Such studies can

inform how climate may have affected the development of the epidemic, as well as the impact of population size reduction on the environment. Ice core analysis and dendroclimatology are both promising in this area.

The scientific study of skeletal remains of plague victims is probably the area with the most potential for future research. Bioarchaeological studies have already produced insightful results on the mortality patterns associated with plague epidemics, but the studies performed to date do not provide definitive conclusions about the epidemiology of the disease across the course of the second pandemic. In the absence of mutations accountable for higher virulence in ancient strains of *Y. pestis* (Spyrou et al. 2019), the factors that made the Black Death so deadly are still to be fully characterized, as are the reasons why the mortality rates decreased in later plague outbreaks. Future studies should address these questions, by expanding anthropological analysis to samples from different areas and time periods to track geographic and temporal differences in plague mortality patterns by age, sex, pre-existing health condition, and other biological factors. If differences are found, they will provide greater insight on how environmental and socioeconomic background influenced the mortality associated with the disease. Archaeogenetic research on both the bacterial strains and human hosts will also be fundamental in reconstructing disease dynamics. Analysis of a growing number of ancient *Y. pestis* strains will permit a detailed reconstruction of phylogenetic history of the bacteria, and help to refine scenarios about the spread of the disease in the various regions of the Old World. On the other hand, comparison of the genomes of Black Death victims with those of post-Black Death individuals has the potential to reveal if host genetic factors played a role in the immune competence of medieval populations and in the overall mortality level during the Black Death.

In addition to improving understanding of the factors acting upon plague epidemiology, bioarchaeological research can provide evidence for the aftereffects of the Black Death on living conditions, health, and life expectancy in medieval populations. Temporal trends in health and survival may be revealed by comparison of pre- and post-Black Death skeletal samples from the same site or locality, but few anthropological studies have investigated this question so far. The results of these studies suggest that both survivorship and health improved in the London population in the aftermath of the epidemic (DeWitte 2018). Further investigations on other burial sites, from distinct geographical backgrounds, are now needed to assess if similar improvements in living standards also occurred in other cities and in the countryside, in England and elsewhere. Future research would be enhanced by including stable isotope analysis to provide direct measurements of changes in diet between the pre- and post-epidemic periods. Combined with molecular data on the gene pool of the survivors, this approach could ultimately reveal how the Black Death shaped the biological characteristics of late medieval European populations.

The Black Sea

Preslav Peev
Institute of Oceanology, Bulgarian Academy of Sciences, Varna, Bulgaria

Introduction

Since the end of the nineteenth century until now, a significant amount of information has been accumulated about the port system of the West Pontic coast. Nevertheless, the complex interdisciplinary approach which contributes to the full and qualitative clarification of the cultural and historical development of the present Bulgarian coasts and their immediate hinterland is not yet fully implemented. The issue of the nature, functions, and external view of the antique and ancient port basins of the Western Black Sea coast has been practically ignored.

To properly understand historical events, it is not enough to only know what happened and when it happened but also where it happened and how the particularities of a given place have affected the course of the event. It is necessary to know not only the person and how he had lived but also the environment where he was active, in other words in what conditions he had lived through different historical periods and in different places. It is necessary to study the geological, climatic, and other physic-geographic features, the flora and fauna of a given place at the moment, and the changes that have occurred there in the past. Otherwise stated, the archeology of the environment or geo-archeology makes us familiar to the history of people's attitude toward the Earth and to the subject of interest – to the matter of the attitude of the coastal population to the sea in general.

Moreover, there is no reason the coastline be considered only as a stretch of land and, respectively, the shelf only as part of the seafloor relief. It is necessary to take into account the fact that throughout all their historical development, these genetically related territories have been dewatered and inundated repeatedly. Therefore, the overriding task here is to clarify the natural conditions over the centuries and their impact on the port system and, on the other part, on the ancient navigation and trade.

Geography

The Black Sea (Fig. 1) covers an area of 466,200 km^2, while its catchment basin's area is of 1,874,904 km^2, of which 0.817 million km^2 belong to Danube River, representing 43.57% of the total. The total length of Black Sea catchment area's watersheds is of 11,200 km, of which 8650 km is on European territory. The Black Sea basin length between Burgas, Bulgaria, and Poti,

The Black Sea, Fig. 1 Map of the Black Sea. (Source: Google Earth Pro)

Georgia, is of 1200 km, while the maximum width is of 610 km and reached the Western part of the basin, between Oceanov, Ukraine, and Eregli Cape, Turkey. The average width is 367.82 km. The maximum depth of the Black Sea is 2245 m, according to the first Russian expedition data. Recent measurements identified a maximum depth of only 2212 m (Vespremeanu and Golumbeanu 2018: 27–47).

In the Holocene Epoch, changes in natural environment on the Black Sea basin varied from region to region. Therefore, the complete paleogeographic reconstruction of the terrain, including the coastline, needs data from different fields of knowledge – geology, geomorphology, paleoclimate, and archeology. Data obtained from underwater surveys are of particular importance for this study.

The development of the relief in the littoral zone is a result of the complex interaction of endogenous (internal) and exogenous (external) factors. Vertical movements of the lithosphere and the hydrosphere can be unidirectional or with a different sign. A number of coasts are characterized by slow positive or negative tectonic movements influenced by sea level fluctuations which are conditioned by climate change, water balance, the impact of gravitational interaction, intense sedimentation, and geoidal eustasy.

Changes in climate cause global cyclic periods of cold and warmth that have a significant effect on the sea level, which in the ages of maximum glaciations has dropped to 100–500 m below the present level. There are a number of hypothesis trying to explain climate changes as a result of solar radiation oscillations during astronomical cycles, self-oscillations due to the development of glaciers, self-oscillations due to decrease and increase of plant biomass, migration of geographic and magnetic poles, and changes in the composition of the atmosphere. It should be noted that the littoral zone during the Holocene was mainly controlled by eustatic fluctuations of the sea level complicated by tectonic movements as this factor has been manifested regionally.

Geology, Paleogeography, and Black Sea Level During the Holocene

The Black Sea is a unique water body with very specific features and characteristics that distinguish it from other sea basins. Even the origin is not fully understood by geological point of view. Till the end of the 1970s, the geological history of the Black Sea is considered by positions of fixistic ideas of the Russian Earth Science School. Since the early 1980s, attempts have been made to apply the new plate tectonics.

It is considered that the Black Sea depression was formed after the Cretaceous period not earlier than 65 million years ago. The Mesozoic surface of the Western Black Sea bed goes beyond its modern boundaries and continues in the Babadag Cretaceous decrease in Northern Dobrudzha, Romania, as well as in the Lower Kamchiya and the Bourgas decrease in Bulgaria. The central structure of the region is the Black Sea Plain, which is considered to be one of the many tectonic depressions of the ancient Tethys Ocean (Hristova 2016).

From the Middle Miocene to present time, the Black Sea depression has developed as a single structure, but the thickness of Miocene sediments in the Western Black Sea trough is twice as low as the Eastern Black Sea, where the thickness is 2 km. The Neogene and Quaternary deposits occur horizontally in the central part of the Black Sea as they blend to the land. During the Pleistocene-Quaternary, the sinking of the seabed continued, and the sediment thickness is greatest in the northwestern part of the Western Black Sea trough, where it reached 3 km (Hristova 2016).

The interest in the Holocene changes at the level of the World Ocean is determined by the impact they cause on the human existence and its socioeconomic development. Although that in terms of the Black Sea region a significant number of publications have been devoted to this problem, the lack of relation of the results obtained for the Black Sea and these of the Mediterranean Sea is noteworthy. The interdisciplinary approach used to solve the problem suggested the involvement of geological, geomorphological, archeological, and historical methods, data, and information. To this end, a thorough analysis of the existing literature, including the latest data from deep-sea studies, has been made.

In recent decades, archeologists, historians, geologists, and geographers are increasingly paying attention to the fluctuations of the Black Sea level. This interest is dictated by the aspirations to satisfactorily explain one or another event or phenomenon related to the geological or human history along the Black Sea shores. In most studies, an attempt was made to include archeological materials to prove a hypothesis or claim. Undoubtedly, archeological data is one of the most reliable and undisputable evidence of changes in the contours of the coastline.

Climate changes cause planetary cycling of warm and cold spells that affect the sea level. However, during the Holocene, the littoral zone was mainly controlled by eustatic sea fluctuations. In the Quaternary (the last two million years), the connection of the Black Sea with the Mediterranean and the Caspian Sea has been periodically cut off and restored which has led to a change in the salinity of the basin and alteration of the halophilic Mediterranean molluscan fauna with the euryhaline Caspian brackish-water one and vice versa. In the transgressive phases of the Caspian Sea, there was a one-sided outflow from the Caspian to the Black, Marmara, and Mediterranean seas, thus forming a peculiar cascade of seas occurring in the conditions of the low level of the World Ocean and the Mediterranean Sea during the glaciations. During the interglacial optimum, a maximum transgression of the World Ocean and flowing of Mediterranean water through the Dardanelles, the Marmara Sea and the Bosphorus into the Black Sea has occurred. The Black Sea transgressions were synchronous with those of the World Ocean because then the connection between them was restored.

During the Würm III glaciation (25,000–17,000 cal. years BP), the New Euxinian stage of the Black Sea geological history came, when the level of the World Ocean dropped to 120 m below the present level. On the place of the Black Sea, the New Euxine lake-sea

was formed. Brackish-water molluscan communities, psychrophilic and freshwater Diatomeae and Dinoflagellata, developing in low salinity and low temperatures were predominant there. The modern continental shelf and the Azov Sea were occupied by extensive alluvial valleys. The littoral zone of this lake-sea was marked by a series of accumulative shoreline or barrier banks – sandbar type, located at depths of 20–120 m below the modern sea level (Fig. 2). Littoral sediment deposits of thickness from a few centimeters to 1 m were discovered. Shellfish aleurite and marl New Euxinian deposits contain a characteristic molluscan fauna among which the *Dreissena rostriformis distincta* (75%) species is predominant.

At that time, the connection between the Black Sea and the Caspian Sea took place through the Manych Strait, which existed until the end of the Pleistocene in the place of the present Manych Depression. The transgressions of the Black Sea and the Caspian Sea were opposite in phases due to the isolation of the Caspian Sea from the World Ocean. Unlike the Black Sea, during a climatic optimum, the level of the Caspian Sea was higher than the Black Sea because meltwater of the Peri-Caspian Depression drained there (Chepalyga 2005).

In the central shelf zone, New Euxinian deposits differ significantly both in thickness and composition. They are presented by gray soft-plastic aleurite loam with shellfish and shellfish detritus. In the sections, a molluscan community of poor species composition is established: *Dreissena polymorpha Pall* (over 50%), *Clesiniola variabilis Eichw,* etc. Their thickness reaches 20 m. The distribution of the New Euxinian deposits of the shelf reaches to isobaths of 28–30 m.

The New Euxinian regression covers the time interval from 30000 to 8000 cal. ago. The level of the then low-saline freshwater lake reached up to 100–115 m below the present level. The geophysical image shows a vast gulf that has existed in the area of the then Danube delta. The basin is of the lake type where deepwater lake sediments have been deposited. Such underwater landscapes are observed almost everywhere

The Black Sea, Fig. 2 Image of old Black Sea shoreline east of Emine Cape. (2009 expedition, RV "Akademik") (after Peev and Hristova 2016)

on the periphery of the continental shelf in the western part of the Black Sea coast.

One of the proofs that it is the Late Pleistocene to Early Holocene coastline is the mussel bank discovered in 2002. During deep underwater diving, it was discovered at a depth of 148 m, which marks the underwater part of the Early Holocene coastline for sure. Most likely, these are the shells of *Mytilus galloprovincialis*, a species living at low depths (Peev and Hristova 2016: 477).

During the glacial epochs, the level of the World Ocean was considerably lower than in modern times, as at that time coastal landscapes that were attractive to human settlements have existed. The early Holocene coastline of the Black Sea basin passed in front of the abovementioned accumulative sand formations.

In this paleographic situation, it became clear why in today's Bulgarian lands there is no data on Mesolithic habitats, with the exception of Pobiti Kamani, Varna District. However, this site cannot be stratified, and the finds discovered there are attributed to the above epoch only through comparison. During the Late Paleolithic and the Mesolithic ages, today's Black Sea shelf was a vast valley watered by many rivers. Even if it is not assumed that the 100–120 m isobath was the ancient coastline, but as it is more popular – 40–45 m – it is again clear that a large part of the shelf has been a land. Therefore, the Mesolithic man's settlements could be found at the bottom of today's continental shelf and more precisely in the areas where the Paleo-valleys of the rivers flowing into the Black Sea were situated.

The novelties in underwater archeology and the other sciences studying the past of the Black Sea pose the question of the oldest navigation in the Pontus in a new light. In the establishment of the regular trade contacts with the Eastern Mediterranean, one cannot overlook the issue of the last connection of the Black Sea with the Marmara and the Aegean seas and the formation of the Black Sea-Mediterranean corridor.

The history of the Black Sea since the time of the last Würm III glaciation is of particular interest. The first thing worth mentioning is that there is no consensus among scientists about the pattern of sea level changes from 28,000 to 25,000 cal. years BP. Some researchers such as Arhangelskiy and Strahov (1938) and other authors more recently Aksu (Aksu et al. 2002: 4–10) think that the New Euxine lake has been gradually transformed into a sea basin and has been recolonized by the Mediterranean organisms during the post-glaciation transgression of the World Ocean. According to these scholars, the transgression began about 9500 cal. BP, when the two-way flow through Bosphorus between the Black Sea and the Marmara Sea was established.

In the 1990s, geologists and oceanographers created a new model of the Black Sea formation and evolution during the last few thousand years. The formation of the Black Sea as a saline-water basin may have happened later than previously assumed. This group of scholars (Ryan et al. 1997; Major et al. 2002, etc.) assumed that the transformation has not been gradual, but abrupt. In their opinion, the transformation of the lake into saline-water basin was a real ecological disaster for the world of the freshwater organisms. The studies of the sediments from the seabed reveal that the lower layers contain remains of freshwater organisms and those overlying them – of saltwater, deposited after the transformation of the freshwater lake-sea. The most interesting is that between these layers there is practically no (or it is minimal) separating zone. This suggests that in terms of geology, the change has happened very quickly. About 7600 cal. years BP, there was an event in the Black Sea that had huge consequences for the ecological situation in the then freshwater lake. This geocatastrophic event is conditionally and completely unsuitably called by some archeologists "Noah's Flood" (Ryan and Pitman 1998; Dimitrov and Dimitrov 2003). Then an abrupt rise of the Black Sea level has started until its alignment with that of the Marmara Sea and the World Ocean.

According to a third scenario (Fedorov 1978, 1982: 151–156; Balabanov and Izmaylov 1988: 54–62; Balabanov 2006: 711–730; Yanko-Hombach 2006: 146–203, etc.), the transition from a freshwater lake into a sea was not gradual or catastrophic but fluctuating, i.e., during the last 18,000 years, there were

The Black Sea, Fig. 3 Black Sea level changes over the last 20,000 years. (After Chepalyga 2002)

periods of rapid rise of the Black Sea level as well as regressions (Fig. 3).

The good conservation of the New Euxinian littoral formations at 100–120 m below the present level is indicative for their sudden inundation and bringing out of the wave influence. At the Pleistocene-Holocene border, Mediterranean waters of 35‰ salinity, having in mind that until then the salinity of the sea-lake was 5–7‰, flowed into the Black Sea over the Bosphorus threshold. According to some calculations (Ryan and Pitman 1998: 141–144), the spilling of Mediterranean waters had catastrophic consequences for both the coastline and the organism world.

About 10,000 years BP, the level of the World Ocean was about 44 m lower than the present level (Lambeck 1996: 601), as during this period for the Black Sea it was significantly lower – about 90–115 m below the present level. As noted, according to recent studies, the formation of Holocene deltas of the rivers started about 8000 years ago, when, according to the isotope curve and the curve of the sea levels, a sudden rise (ranging from 5 to 15cm/year) of the level with about 14 m is indicated (Stanley and Warne 1994: 228–231). In the Black Sea, this transgression is called New Black Sea transgression.

In the publications related to the problem of the Black Sea level fluctuation, no comparison of the Aegean and the Mediterranean data was made. In works devoted to the subject (Fedorov 1978), without detailing the situation for Antiquity and the Middle Ages, some points related to the eustatic fluctuation of the Black Sea during Holocene have been considered. As a rule, these publications follow the traditional scheme established as early as in 1950s and 1960s. The issue has been examined more thoroughly by Lazarov (1975: 37–38, 125–134) and especially by Filipova-Marinova and Hristova (2001: 59–64) and Peychev and Peev (2006).

Zenkovich in his monograph "Morphology and Dynamics of the Soviet Coasts of the Black Sea" (Zenkovich 1958) thinks that during the postglacial time, the Black Sea level did not exceed the present level. Initially the pace of the Black Sea transgression (about 8000 BP) was high, but subsequently it became slower.

In the central part of the continental shelf, Lower Holocene (Bugazian) littoral facies of sandy gravel sediments with shellfish detritus at an absolute depth of 30–34 m were revealed. Probably, within this interval, there was also the Early Holocene coastline. C^{14} absolute age at the bases of the Lower Holocene layers are 7480 ± 540 и 8080 ± 20 BP. Sediments situated above are dated 6890 ± 630 (Dimitrov 1982: 46).

During the coring in the mouth of the Veleka River at the interval of 42.10 m up to 26.9 m in the lagoon-firth deposits on the *Cardium-Mytilaster* complex, there has been made radiocarbon dating. They show an absolute age of 9945 ± 160 BP and 8355 ± 75 BP (Filipova-Marinova and Hristova 2001: 59). The rise of the sea level from 40 to about 12–15 m below the present one is also noted at the formation of

the seaside lakes along the west coast of the Black Sea.

There are a number of sunken prehistoric settlements known to be found on the west coast of the Black Sea, which in the scientific literature have long not described as "pile dwellings." Recently, in some works, there has been an attempt to precisely establish their nature.

The remains of the eight submerged settlements from the second phase of the Eneolithic Age (Ivanov 1993: 19–26) and one in the aquatory of the Sozopol Port (Draganov 1995: 233–239) were found on the banks of the Varna-Beloslav liman. The main results of the studies made indicate the presence of two cultural layers (Eneolithic and Early Bronze), without establishing residential horizons, known from the cultural deposits of the land. The piles of residential buildings have remained in place and later gave the wrong idea that they are part of a platform on which ancient dwellings were built.

In contrast to Varna-Beloslav Lake, along the southern Bulgarian coast, two of the submerged prehistoric settlements – in the aquatory of Sozopol harbor (Draganov 1995: 233–239) and at Urdoviza Cape (Draganov 1995: 226–233) – have been studied with a relative success.

The Eneolithic settlement at Sozopol belongs to Kodjadermen-Gumelniţa-Karanovo VI and the Early Bronze one – to the 6th–5th horizons of the Ezero tell (Draganov 1995: 236). The depths at which cultural layers are found are 6–9 m. Recent studies on the situation of the prehistoric settlements of the west coast of the Black Sea unambiguously show that they were located on the first unflooded river terrace (Peev 2004: 164) and not on wooden platforms as it is widespread in the archeological literature. Chronologically, they refer to the culture of Varna (Todorova 1984: 41, 45–51) and existed in the second half of the fifth millennium BC, which undoubtedly proves that during this period the Black Sea level was certainly lower than the present one with at least 9 m for the time interval of 4600–4100 cal. BC.

Life in these most developed settlements in the world for their time abruptly stopped at the very end of the fifth millennium BC. One possibility is that this has happened as result of a natural disaster in which the settlements of the bearers of the Varna culture were flooded. Evidence of a sudden rise in the Black Sea level at that time we find at these submerged Eneolithic settlements. The dredging works in the area of Varna Lake and the underwater archeological excavations of Arsenala settlement and Sozopol revealed wooden piles of dwellings with preserved bark and numerous ceramic vessels and tools which have been very precious for their time. If the water has been rising slowly, people would have been able to took them, and if the settlements ceased to exist as a result of an invasion of steppe tribes that came somewhere north, it is unlikely the invaders to have left them.

After the abrupt rise of the Black Sea level at the end of the fifth millennium BC, there is a new regression that lasted until the end of the third millennium BC. The settlements were situated on the unflooded terraces of the then river valleys, except, probably, for the village located near Cape Ata. The established Black Sea coastline during the existence of the prehistoric settlements in the Late Eneolithic Age was 9–10 m below the present level, and in the Early Bronze Age, it was at about 8 m. At that time, modern coastal lakes were still sea bays and were not separated from the sea by sandspits. The latter is tied to the rising sea level and lasted to Antiquity as described by the ancient authors (*Polyb.* IV, 41; *Str.* I, 3, 4).

According to Fedorov (1978) on the coasts of the Black Sea and the Sea of Azov, there are New Black Sea terraces with a height of 3–5 m and age of 3500–4000 BP and Nimphean terraces with a height of 1 m and age of 1500 BP, as, between the time of their formation, the Phanagorian regression took place. After the Nimphean transgression, the level of the Black Sea decreased (Korsun regression), and in the last few centuries it has been slowly increasing (Laz transgression).

Geological evidence for a significant rise of the Black Sea level is found on the northern Bulgarian coast. On the terraces from the area of Balchik Tuzla and the town of Kavarna, shellfish are dated 5140 ± 270 and 5650 ± 100 BP, respectively (Krystev et al. 1990: 212).

Most likely, the terraces, which are interpreted as indicators for sea level rise of up to +4 and +5 m above the present one, are the result of tsunami waves. There are no data from the Mediterranean for such an abrupt rise of the World Ocean. Tsunami waves have been observed in the Black Sea continuously, even in prehistoric times. The Byzantine chronographer, Theophan, describes such a disaster that came upon Odessos, Dionisiopolis, and Aphrodisia in 544 AD (*Theoph.* 537).

After the eventual abrupt rise of the Black Sea level at the end of the fifth millennium BC, there is a new decrease (regression) that continues to somewhere until the end of the third millennium BC.

From the Pitsunda Cape at the Abkhazia coast, Balabanov et al. (1981: 90) mark a level of −6–6.2 m in 5240 ± 96 BP. From the Bulgarian coast, settlements of the Early Bronze Age of the Varna-Beloslav Lake, Atia Cape, Sozopol, Ropotamo, and Kiten are known. Their cultural remains are found at a depth of about 5–6 to 8–9 m at Kiten, which corresponds entirely to the data from the Mediterranean coast. The pottery form Urdoviza is identified as typical for the Ezero tell and is referred to the 8th–5th horizons. Eighteen radiocarbon datings refer Kiten (Urdoviza) to the second phase of the Early Bronze Age together with Ezerovo II and Mihalich phase of the Ezero culture from Thrace. According to them, the time interval of the existence of the settlement is 4180–4040 BP (between 2850 and 2600 cal. BC) (Görsdorf and Boyadzhiev 1996: 157–158).

The subsequent rise of the level of the Black Sea at the end of the third millennium BC is traced by the interruption of the life in the coastal settlements from the Early Bronze Age. At Rybakovka village, Odessa region, Ukraine, in the area of the sandspit of the Berezan liman, there is a terrace of 2 m above the present sea level. This is the only site from which a sample was taken and a radiocarbon dating was made. The age of the terrace is 3900 ± 100 BP (Konikov 2006). A sounding revealed 0.90 m of modern diluvium from the slope and under it typical marine deposits with thickens of 1 m and at the bottom buried beaches. Konikov (2006) believes that this is the undisputed proof of a transgression of about 1.5 m above the present sea level.

The humid period that began in the Neolithic Age ends in the third millennium BC. The drastic change in climate affects the economy and the life in Egypt and coincides (perhaps not accidentally) with the weakening of the central government and the straightening of the provincial aristocracy and nomarchs in Ancient Egypt.

In the area of Balchik Tuzla Lake on a 5-meter-high terrace, shells from *Ostrea edulis* L. are dated to 3120 ± 50 BP (Krystev et al. 1990: 214). It should be noted that nowhere else in the Black Sea region or in the Mediterranean region is there an evidence of such a rise in the sea level.

In the Late Holocene (the last 3000 years), the coastal morphology is controlled by the sea transgressions and regressions as evidenced by the submerged ancient ruins (Flemming 1978). This is the case with the Black Sea.

When restoring the coastline since the ancient times, it is extremely important to determine sea fluctuations. Due to the scant data we have for the operation of the port basins along the Western Black Sea coast, this information is of great value. For example, a huge number of stone anchors of the second millennium BC have been discovered along the Bulgarian coast. The science refers them to the shipping during the Late Bronze Age. Since until now there are no ports of this age established with an absolute certainty, involvement of geomorphological and underwater surveys could support searches in this direction.

Many of the stone anchors mentioned above have been discovered in areas that do not imply the presence of a port basin today, because they are not sheltered from sea storms. However, if we restore the ancient coastline, we will see that at least one of them (Caron Limen) has had a natural protection from the strong northeastern and eastern winds. This site will be discussed in details in the following entry. Nowadays, at Shabla Cape there is a 400-meter-long pier which is set on a reef with a maximum depth of 4 m in the its eastern part. At these levels of the Black Sea, the reef was apparently at the level or slightly above the level of the sea.

The so-called Phanagorian regression began in the middle of the second millennium BC and lasted until the Late Antiquity. The Black Sea level during the Late Bronze Age was approximately about −1.6 to −5 m below the present one. The period from the beginning of the first millennium BC until the sixth century AD is characterized by low global temperatures. The river outflow has decreased a lot, and as a result the level of the Black Sea basin has dropped. The peak of the Phanagorian regression should be referred to the fifth–third century BC. According to various authors and the interpretation of the facts, the maximum varies from −2–3 m to −11 m below the present sea level. According to Xant (*Xant*), during the time of the Artaxerxes III of Persia (465–425 BC), "there was a great drought." This fact is also a support for the peak of the Phanagorian regression, which we refer to the fifth–third century BC.

In general, the Black Sea level at the beginning of this period (sixth century BC) is fixed at −4 m to reach up to −2 to −3 m at its end (sixth century AD).

The next stage of the changes in the Black Sea level is the Nimphean transgression. This period (the eight- the middle of the tenth- century) we assume as the maximum of the transgression for both the Mediterranean and the Black Sea. All ports on the Bulgarian coast cease to operate by the end of the sixth and the beginning of the seventh centuries. The conclusion is that from the Late Antiquity onward, there is a rise in the sea level. It is associated with the Nimphean transgression, which is a reason for the flooding of the ports and parts of the ancient towns along the Black Sea coasts.

As mentioned above, probably in 544, some Western Black Sea towns were severely hit by a tsunami wave, followed by a great earthquake (*Theoph.* 537). Theophan listed Odessos, Dionisiopolis, and Aphrodisia. It is very likely that other ports were damaged as well, and this might be one of the reasons for them to cease operation.

After the sixth century, there was obviously a relatively rapid rise of the sea level. The foundations of a Chersonesus tower from the sixth to the beginning of the seventh century are at a depth of −1 m, and the peak of the Nimphean transgression is referred to the seventh to eighth century. However, as we mentioned above, we consider the maximum of the transgression to be in the eighth to the middle of the tenth century. The medieval Develtus, located west of the Mandra Lake, was still a port city at the beginning of the eighth century. As the Byzantine historian Niketas Choniates wrote, in 1203, the depositioned Byzantine emperor Alexios III Angelos (1195–1203) arrived in the city by boat.

Later there was a drop in the sea level. This is the so-called Korsun regression named after the town of Korsun (the ancient Chersonesus). However, the existence of such regression is quite controversial. Data are mainly gathered from the northern shores of the Black Sea as the peak is set to −3–3.5 m (Shilik 1997–1999: 25). Indeed, some of the results obtained support this view – for example, walls and towers of Chersonesus from the eleventh to twelfth century, another tower again from Chersonesus from the thirteenth to fourteenth century, the foundations of the St. Nicholas Church from the end of the fifteenth century at Kiliya, discovered at a depth of −2.5 m below the present sea level (Shilik 1997–1999: 25). However, there is no such data from the other parts of the Black Sea and the Mediterranean coasts. Probably there were local neotectonic movements.

In this case, it would most aptly be spoken of as a mild eustatic drop in the Black Sea level, which is a result of the general cooling of the climate in Europe in the thirteenth and fourteenth centuries (Hay et al. 1991: 1211–1235).

However, there had obviously been a water level decline, and we find evidence of this in medieval and Renaissance sea maps. These considerations are fully supported by the maps of the thirteenth to eighteenth centuries where the coast is presented in details.

The current rise in the Black Sea level began in the second half of the seventeenth century. This is the so-called Laz transgression. The formation of a sandspit at the mouth of the Batova River is dated according to a complex of *Donax trunculus*

(L.), Chione gallina (L.), and others to 290 ± 90 BP (Krystev et al. 1990: 215).

The comparative analysis and the interpretation of the various data imply the following conclusions:

The fluctuation of the Black Sea level is among the main factors for coastal evolution, and it, in turn, is controlled by the level of the World Ocean.

Based on the existing data, a Black Sea level curve for the past 12,000 has been drawn up, which will be further refined with the production of new data. In this thesis, this is the first time a comparative analysis of the data from the Black Sea and the Mediterranean Sea is made, which significantly changes some of the former perceptions.

In the analysis of the received curve, the nonexistence (or at least not in the mentioned dimensions) of the Korsun regression, widely described in scientific literature, is noticeable. In this case, we could talk about a slight drop in the sea level due to the cooling of the climate in Europe.

History and Archeology

Cultural and historical development of the societies in the Antiquity is determined by a number of factors, which influence them independently and as a whole – geographic factor, demographic factor, means of production, religion, etc. Disregarding or amplifying the influence of just one of them will inevitably lead to distortion of the historical reality in the interpretation and reach the wrong interferences.

The task here is to trace the main stages in the history and culture of the Western Black Sea coast within the context of the common Mediterranean history. In this regard it should be noted that the sea has always been a distinct area – aquatory – region, defined by overseas connections, commercial, military, and political, including the migration of people and ideas (King 2006: 27–28). In the millennial history, coastal and hinterland communities have long been influencing each other and the geographically remote regions of the Mediterranean (mostly Eastern ones), which have reflected on the sociopolitical life, economy, religious beliefs, and folklore.

Periodization is necessary when studying historical reality. Methods may be different, so that differences may be possible when periodizing the past, including the cultural and historical development of the Western Black Sea coast.

The period ninth/eighth to fifth millennium BC (Neolithic and Eneolithic) is characterized by climatic optimum, which was the prerequisite for the rapid development of the human society in economic and cultural terms. The climate is warmer and more humid, and this has altered the lifestyle of the inhabitants of the Middle East and Southeast Europe. This is the time of blooming of the brilliant Neolithic cultures in Southeastern Europe and Asia Minor to reach their apogee through the Chalcolithic period and to unexpectedly wane at the end of the fifth millennium BC. At the end of the period, a social stratification is observed. The higher and most striking expression of this ideology of the Late Eneolithic society of Southeastern Europe is the Chalcolithic Necropolis of Varna and in particular burial site No 43. In this order of thought, the ancient Thrace civilization is asynchronous, earlier in time and similar in meaning to the ideology of the Old Kingdom of Egypt.

The earliest traces of statehood in Thrace are visible at the metallurgical center near the banks of the Varna Lake (especially the golden ornaments from the Chalcolithic Necropolis of Varna; from the so-called Palace Complex on the Big Island of Durankulak; from the giant for their time copper mines in the area of Mechi Kladenets, the region of Stara Zagora and Strandzha coast; from the fortification facilities (palisades) in some villages; etc.) The bloom of this community is based on the extraction and trading mainly of copper, gold, and salt.

However, if we are speaking specifically about the Western Black Sea coast, it could not be noted that Copper Age civilization was connected with the sea and has developed maritime trade. This is evidenced by the spread of copper and copper products far north of the mines of Thrace – in the Black Sea steppes – the numerous shells of the Spondylus, *Dentalium*,

and *Glicerimus* mollusks in the northeastern part of the Balkan Peninsula and along the Danube River to Central Europe; and remnants of fishing and clay figurines of vessels.

The so-called Transitional Period (Middle Neolithic) (4150–3200 cal. BC) stands between the Eneolithic and Early Bronze Age. Despite the favorable climatic conditions on the Western Black Sea coast, according to data of the palynological studies, there is no evidence of human activity (Filipova-Marinova 2006: 35, 50). This confirms the existence of a hiatus of about 800 cal. years between the late Eneolithic and early Bronze Age. Todorova shortens this period by introducing the terms of "Post-Chalcolithic" and "Proto-Bronze Age" (Todorova 1995: 89–92).

Undoubtedly, the cultures of the Balkan Peninsula coast, Asia Minor, and Aegean islands are inextricably bound up with sea in the Early Bronze Age as well. This is evidenced by the numerous coastal settlements where the fishery as a livelihood occupies a much more significant place in the economy than in the Chalcolithic as well as the established Circum-Pontic and north Aegean archeological communities. In the Early Bronze settlements on the Western Black Sea Coast lives a population that knows, values, and can take advantage of the resources offered by the sea.

In the third millennium BC, Egyptian merchant fleets constantly visited the ports of the Red Sea, the Land of Punt, and the eastern Mediterranean coast – North Africa, Syro-Phoenician coast, Cyprus, and Crete. What is the probability that Egyptian ships have visited the Western Black Sea coast? The hypothesis is supported by the evidence of commercial contacts between the Western Pontus and the Eastern Mediterranean in the second millennium BC. Such archeological contest, though dated to the Late Bronze Age, is created by a number of finds – metal oxhide-shaped cake ingots, the silver needle from Medgidia, the golden tiara from a Hellenic tomb in Odessos, etc.

The almost identical historical development of Thracian lands established the scientific use of the *terminus technicus* "Mycenaean Thrace." In fact, the first author to use the term "Mycenaean Thrace" was Filov in 1920 (Filov 1920: 40–53). State-forming processes similar to those in the Achaean states are also observed among the local Thracian tribes. In this sense, the Western Black Sea region, and thence the banks of the Lower Danube, together with the valleys of Struma, Mesta, and Maritsa, cover this term more fully.

The second half of the second millennium BC (the Late Bronze Age) is an extremely dynamic period in the history of the Black Sea and the Eastern Mediterranean region. This is the time of the bloom of the bronze metallurgy and the trade of its products. Moreover, during these centuries, Thracian tribes consolidated, and the Thracian civilization, which was included in the common for the then world political, economic, and cultural relations, was formed (Bonev 2003).

There are already a lot of monuments and finds from the Balkan Peninsula supporting the idea of Mycenaean Thrace. An oxhide ingot is depicted on a pottery discovered in a prehistoric settlement near Burgas, Bulgaria; the metal ingot from the village of Cherkovo, Burgas area; bun ingots from aquatory of Maslen nos Cape; copper oxhide ingots discovered in Razgrad District; and ingots from Ruse and Elhovo area, Bulgaria (Bonev 2003; Leshtakov 2007). As a result of the parallels drawn with the finds from the Mediterranean, chronologically the ingots of Cherkovo, Kaliakra, and Ruse could be referred to fifteenth to fourteenth century BC and those from Razgrad area to fourteenth to twelfth century BC.

Here is the place to mention the Achaean presence in the written monuments found in the Black Sea. The most known writing is the myth of the famous Journey of the Argonauts in search of the Golden Fleece, described by Apollonius of Rhodes in his Argonautica (*Ap. Rh.* Argon.). In this particularly valuable to us source, the author supplies information about the nations inhabiting the lower course of Istros and provides extremely important information on early navigation in the Black Sea from the second half of the second to the end of the second or the beginning of the first millennium BC associated with the legendary Journey of the Argonauts.

He lived in the third century BC but brought us back the events that have happened at the end of the second to the beginning of the first millennium BC. The ship itself was equipped with a sail and ten oars. Argonautica makes reference to the early penetration of Aegean people in the Black Sea basin. But as mentioned above, there is archeological evidence for the appearance of Mediterranean seafarers dating back to the sixteenth to fourteenth century BC, a few centuries before the Argonauts.

Other Greek legends also mention contacts of East Mediterranean peoples with the population along the Black Sea coast. For example, such is the story of the stay of Odysseus in the country of the Cimmerians (Odyssey, books X, XI, and XII – B. Dimitrov suggests that the action takes place in the Black Sea); the myth of the stay of Achilles on the Island of Leuke (present-day Zmeinÿi, Ukraine) at the delta of Danube River (*Arktin of Miletos* Aeth.; *Arr.* PPE 32–34); and the myth of the stay of the daughter of Agamemnon – Iphigenia – in Tauris (*Euripides* IT). However, myths do not enable us to chronologically specify when in time the Mediterranean ships have entered the Black Sea.

The active navigation on the Western Black Sea coast is marked by the numerous stone anchors, the metal ingots bun, and oxhide-shaped models and images of vessels. Of course, the images and models of boats can be related to the Solar Boat and have a purely cult purpose (Bonev 2003: 42, 43), but ingots are indisputably commercial in nature and have been imported or exported from the Thracian lands by ships. In Diodorus Siculus (?–35 BC), the author of *Bibliotheca historica* (consisting of 40 books), we find the well-known in the science of history information about the Thracian Thalassocracy in Aegae (VII, 13). Although it refers to the Aegean Sea, this information is particularly valuable with the confirmation that Thracian tribes were actively engaged in navigation.

The permanent settlement of ancient Greek communities along the Black Sea coast is referred to the seventh century BC. Some city-states established their colonies (ἀποικία), but no one was able to surpass Miletus (*Plin.E.* NH IV, 29, 112). Miletus was the most prosperous city on the Ionian coast and the main trading center in Aegea. Its colonies in the Euxinian Pont were among the largest and most significant cities: Sinope, Panticapaeum, Olbia, Histria, Tomis, Odessos, and Apollonia (Fig. 4). Another metropolis which founded many colonies is Megara. The Thracian tribes on the Black Sea coast were in direct contact with the Greek settlers, who permanently settled in their lands and thus influenced the overall historical development of Thracia Pontica.

After the middle of the first millennium BC, the development of the ancient Greek poleis not only connected all Black Sea coasts but also included them in a broader system of exchange with the Mediterranean coast. By the fourth century BC, Thrace gradually became an agricultural country by exporting more and more grain and livestock to Hellas. This integration in the common Mediterranean processes continued to the beginning of the first century AD when the southern Danubian Thracian lands were turned into the Roman province of Moesia and Thrace (46 cal.), at that, on the periphery of a vast state.

The victory over the Mithridates VI of Pontus (111–63 cal. BC.) extended the borders of Rome to the Euphrates River. The spread of Roman power to Egypt and Asia to certain extent reduced the importance of the Black Sea ports. In its prime, the early Roman Empire included more than half of the Black Sea coast – from the Dniester River through Thrace to the north, westward to Asia Minor to the south, and Caucasus to the east. So far, on the western coast, the finds from the so-called Italic amphorae from the second century BC to the first to second centuries AD, widespread in the Mediterranean, are very few. In underwater surveys, pottery from this period is discovered, which was mainly made in the southern Black Sea coastal towns located along the Asia Minor coast (Kassab-Tezgör and Tatlican 1998).

The old connections established during the Hellenic resettlement were revived in the fourth century, when, from periphery, the Balkan Peninsula lands became the center of the state and the coastal towns to economically powerful

The Black Sea, Fig. 4 The ruins of ancient settlement Istria, Romania. (Source: Author)

centers. The overseas trade with the forest-steppe area of the Northern Black Sea coast intensified especially after the relocation of the capital to Constantinople (330 cal.), by trading leather, fish, etc. Craftsmanship, trade, and hence the navigation intensified as well, and a number of ports were restored. This is evidenced by the numerous and diverse amphorae and other pottery from the fourth to sixth centuries, which were used for storing goods when transported.

The increased importance of the Black Sea coast is supported by the fact that on 18.V.536, the Byzantine Emperor Justinian I (527–565) made Odessos a center of a vast maritime area with an appointed prefect, which, besides the Western Pontic coast, included Scythia, the Cycladic islands, the region of Caria in Asia Minor, Cyprus, and Rhodes (*Iust.Nov.* 13, III).

Constantinople, whose geographical situation is extremely favorable, kept in its powers the entire trade by the Black Sea, the Archipelagos, and the Mediterranean. Wheat, vegetable oil, salt, leather, iron, iron ore, etc. were imported for the needs of the northern neighbors of the Byzantine Empire – Gothic and other tribes – and furs, copper, and wax were imported.

At the end of the eleventh century, the Black Sea hegemony of Byzantium was broken. The Byzantius fleet experienced more tangibly the influence of the Roman towns – states. Venice was the most active one at the beginning, later followed by Genoa and Pisa. The fight for superiority among the Italians was extremely severe. The Byzantine merchants suffered a hard blow when in 1204 the knights of the Fourth Crusade conquered "the Capital of the World" – Constantinople and the Byzantine Empire disappeared from the historical scene for a certain period of time.

On 13.III.1261 in Nymphaion (Asia Minor), the emperor Michael VIII Palaiologos (1259–1282) signed a trade contract with Genoa. According to its terms, the Black Sea should have remained closed for foreign ships except for Genoa's and Pisa's. Thus the beginning of Genoa's domination in the Black Sea field was set. In 1263 the Venetians defeated Genoa's navy, which supported the Byzantines. Michael

VIII Palaiologos signed a contract with the Venetians, too, on 18.V 1265, which was ratified in 1268. In this way the Venetians received great trade privileges, and the rivalry with the Genoas sharpened. The Emperor, forced to trim, renewed the terms of the Nymphaion contract with Genoa.

In the thirteenth to fourteenth century, Genoa, Venice, and Raguza merchant ships sailed across the Black Sea. The foreign trade of Byzantine was mainly in the hands of Italians. Byzantine fleet was in decline and was almost completely replaced by the strong fleets of the trade republics.

In 1453 the Ottoman Turks conquered Constantinople, an event that led to a delay in the historical development of the whole Southeast Europe. The Turks pushed Italian merchants, who had trading posts in Tana and Kaffa, away from the Black Sea trade in the last quarter of the fifteenth century (e.g., Kaffa was conquered in 1479). With the beginning of the sixteenth century, the Black Sea was closed more than ever and turned into a Turkish lake. Merchants from the town of Raguza gave up trading by the Black Sea, too.

The history of navigation on the Black Sea was being written by the navigators of the Ottoman Empire and Russia during the following centuries.

The Black Sea name (Black Sea, Mer Noire, Mare Nero, Schwarze Mer, Cernoe More, Kara Deniz) is given recently, dating since the medieval times and has no connection with the ancient names – Pontus Axeinus and Pontus Euxinos.

Black, Davidson

Julie L. Cormack
Department of Sociology and Anthropology, Mount Royal University, Calgary, AB, Canada

Basic Biographical Information

Davidson Black, FRS, was born on July 25, 1884, in Toronto, Ontario, Canada, and died on March 15, 1934, in Beijing, China. As a Canadian-trained anatomist and medical doctor, he was best known for his anatomical descriptions and naming of a new fossil human species, *Sinanthropus pekinensis*. Unlike most foreigners, Black got along extremely well with his Chinese colleagues as he treated them as equals and involved them in decision-making. He was known as 步達生 (pinyin: Bù Dáshēng) in China.

His father died when Dyo (as he was known by his family) was 2 years old and was brought up by his mother and uncles. Many summers were spent in the Kawartha Lakes region of southern Ontario, and when he was old enough for employment, he worked as a biological field assistant and a voyageur/fire ranger in forested regions of northern Ontario and later as a mining engineer for the Geological Survey of Canada on Vancouver Island. During these jobs, he got to know his First Nations' friends and was given the name "Mushkemush Kemit" (thought to be an Ojibwe phrase meaning "fast through the forest"). Like his father, he had a fragile heart, further weakened during a bout of rheumatic fever during his mid-teens. He eventually died at the height of his anthropological career at age 49 of congenital heart failure.

Starting in 1903 he studied at the University of Toronto, where he graduated with his Bachelor's degree in Medicine in 1906. He promptly returned to the University to complete his Arts degree, but with a delay in completing language requirements, he formally graduated in 1911. Before convocating, in 1909 he took a full-time teaching position in Anatomy at Western Reserve University in Cleveland, and during one of his visits to his Toronto home, he met Adena Nevitt, his future wife. Adena (second daughter of Richard Barrington Nevitt, a prominent Toronto physician who was a medical doctor for the Northwest Mounted Police) and Davidson married in December 1913. They had two children, a son Davidson (b. 1921) and daughter Nevitt (b. 1925). It was Black's close Anthropology colleague Wingate Todd who recommended that Black travel to England to work with well-respected neuroanatomist (Sir) Grafton Elliot Smith. Black followed Todd's advice during a sabbatical in 1914 when he visited Elliot Smith at his University of Manchester laboratory just as Elliot Smith was pondering the newly discovered Piltdown fossil puzzle. This visit was Davidson Black's first introduction to Anthropology, which fired his scientific imagination! Eventually returning to Cleveland (and with his new contacts in England including Woodward Smith and (Sir) Arthur Keith), Black set about to build anthropological teaching collections. Through this work, Black was introduced to American Henry Fairfield Osborn and the work of fellow Canadian William Diller Matthew, both of whom were intrigued by the potential of Asia as a fossil-hunting ground. Matthew's 1915 writings convinced Black that Asia was central to the search for primate ancestors.

In 1917 (after three attempts to join the war effort, because of his weak heart), Black joined the Canadian Medical Corps and was based at a military camp in southern England. During this overseas experience, unknown to Black, his medical passions were being discussed by members of the American Rockefeller Foundation, an agency that had initiated plans for a "Johns Hopkins" of the East. Black was being considered for the position of Neurology/Embryology professor at the newly conceived Peking Union Medical College, in Beijing, China. This invitation was Black's chance to now fully dedicate himself to the questions of Asian prehistory. In September 1919, Adena and Davidson Black arrived in China.

Major Accomplishments

Davidson Black is often identified as "discoverer" of Peking Man or *Homo erectus* from China. He did not discover these fossil human remains but instead initially recognized three teeth as belonging to a human ancestor that had not been identified previously. In 1927, Black published a monograph in which he named this species – *Sinanthropus pekinensis*.

Black was keen to search for human ancestors in Asia but had to concentrate on his professorial duties. Initially he published scientific analysis of human remains found by his Swedish colleague J.G. Andersson who worked for the Geological Survey of China. In 1926 Black learned of two fossil teeth found near Zhoukoudian (Dragon Bone Hill) village southwest of Beijing. He recognized these two teeth as human and arranged for Rockefeller Foundation funding for systematic excavations starting in 1927. Upon finding a third tooth, in situ, Black was confident in identifying the first-ever fossil human remains from China. By now the College recognized Black's dedication to Anthropology and also the key role that the PUMC along with the Geological Survey/Society of China might make to the human sciences, and Black was allowed to focus his energies on research. Black was central in the creation of a "union" between the GSC and PUMC that became a human origins facility known as the Cenozoic Research Laboratory. Annual excavations by teams of young men and boys resulted in the discovery of numerous teeth and jaw fragments and in 1929 the first evidence of a "complete" human cranium (Skull III) from the site by Pei Wenzhong. Black's responsibility was describing and analyzing these human finds; his papers were published by the GSC and in a journal called *Palaeontologia Sinica*. Davidson Black was the voice for *Sinanthropus* as he travelled to conferences in southern Asia, North America, and throughout Europe, illustrating replica examples and visual images (photographs and drawings) of these fossils to his scientific associates.

Black received numerous honors including:

- Grabau Medal, Geological Society of China in 1929
- Honorary D.Sc., University of Toronto in 1930
- King Gold Medal, Peking Society of Natural History
- Fellow of the Royal Society in 1932 for work on *Sinanthropus* (Croonian Lecture entitled *The Discovery of Sinanthropus*)
- Daniel Giraud Elliot Medal for work on Peking Man from US National Academy of Sciences awarded for 1931, conferred posthumously in 1934
- Recognition of his work in human origins with the species name *Gigantopithecus* "*blacki*"

Blombos Cave: The Middle Stone Age Levels

Christopher Stuart Henshilwood[1,2] and Karen Loise van Niekerk[1]
[1]SFF Centre for Early Sapiens Behaviour (SapienCE), University of Bergen, Bergen, Norway
[2]Evolutionary Studies Institute, University of the Witwatersrand, Johannesburg, South Africa

Introduction

Blombos Cave, an archaeological site situated on the southern Cape coastline, South Africa, contains Middle Stone Age (MSA) deposits dated at between c. 130 and 72 ka (ka = 1000 years ago), possibly the most important period in the early development of modern human behavior. Since 1992 each excavation season at the site has yielded important new information on the behavioral evolution of *Homo sapiens*. This includes, at c. 75 ka, among the earliest known evidence for the manufacture of personal ornaments on shell beads, formal bone tool production, engraving of abstract designs on ochre and bone, the deliberate heating of silcrete, a lithic raw material, and the subsequent manufacture of bifacial stone points on this material using pressure flaking. In the 100 ka levels, a complex toolkit was uncovered that provides the oldest known evidence for the use of containers and for the production of an ochre-rich pigment or paint. These findings from Blombos Cave and subsequent reanalysis and excavation of other contemporary sites have resulted in a paradigm shift with regard to our understanding of the timing and location of the development of modern human behavior.

Definition

In tandem with the anatomical evolution of modern *H. sapiens* in Africa after 200 ka was the increasing capacity for symbolically driven behavior. Exactly when or how this capacity first translates into a material culture that carried symbolic meaning is unclear. Innovative material culture recovered from Blombos Cave provides a clear signal that by 100 ka human behavior was mediated by symbols. This evidence is likely only one part of a behavioral mosaic, a "wind of change" throughout the African Middle Stone Age that culminated in the diasporas at c. 60–80 ka – a series of human expansions from Africa that first introduced fully symbolic *sapiens* behavior to Eurasia and the rest of the world.

Key Issues/Current Debates/Future Directions/Examples

A major research challenge in archeology is identifying when and how symbols were used for the first time to mediate hominin behavior. Once in place, this innovation provided an ability to share, store, and transmit coded information and played a crucial role in creating the social conventions and identities that now characterize human societies. Over the last decade, the Blombos Cave (BBC) results have challenged long-held beliefs that the origins of behavioral modernity and the first use of symbolic material culture lay in Europe and commenced about 40,000 years ago. The focus for modern human behavioral origins has since switched to Africa and now generates lively debate, worldwide. Further analyses of the BBC materials and ongoing excavations at the site continue to contribute to this debate. A new dimension, paleoclimatic reconstruction, has been added to this research paradigm and suggests that the variable climates that characterized the Late Pleistocene had a major effect on the continuity of key cultural innovations. The adaptive responses of *Homo* to changing climates are however poorly understood; researching the role of climate in shaping the cognitive evolution of *H. sapiens* is, therefore, a priority. It is expected that existing and future results from BBC and other nearby sites will provide important information for understanding the development of human behavior within the context of climatic variability in the southern African Late Pleistocene.

Description of Blombos Cave

Blombos Cave lies 300 km east of Cape Town and is situated in a steep wave-cut calcrete cliff, 100 m from the Indian Ocean, and 34.5 m above modern sea level (34°25′S, 21°13′E) (Figs. 1, and 2). It is set into the calcified sediments of the Tertiary Wankoe Formation, and the calcareous environment is at least partially responsible for the good preservation of the recovered deposits (Henshilwood et al. 2001b).

Stratigraphy and Ages

The earliest Later Stone Age (LSA) occupation is c. 2 ka. The MSA levels are divided into four phases comprising a number of discrete layers within each phase (Fig. 3). These phases are named M1, upper M2, lower M2, and M3.

Blombos Cave: The Middle Stone Age Levels, Fig. 1 Blombos Cave site entrance

Blombos Cave: The Middle Stone Age Levels, Fig. 2 Interior of Blombos Cave (Image: Magnus Haaland)

A hiatus level composed of undisturbed aeolian sand above the M1 phase, DUN (Fig. 3), is dated to c. 70 ka. This layer of sand sealed the mouth of the cave and it reopened after the mid-Holocene high sea level stand at c. 4–3 ka. The upper part of the M1 phase dates to c. 73 ka and the upper M2 phase to c. 75 ka. The lower M2 phase layers date to c. 85 ka. The M3 phase dates to c. 100–94 ka and the ages of the lower levels, below level CQ hiatus, are currently being determined. The majority of dates were determined using optically stimulated luminescence (OSL) (Jacobs et al. 2006), but other methods, such as thermoluminescence (TL) (Tribolo et al. 2006) and uranium-thorium (U/Th) (Henshilwood et al. 2011), have also been employed.

Material Culture: M1 and Upper M2 Phases (Still Bay c. 75–72 ka)

The M1 and upper M2 phases fall within the Still Bay complex. Artifacts from these phases include bifacial stone points, bone tools, marine shell beads, and engraved ochre (Fig. 4).

Bifacial Points (Fig. 4a): Still Bay points, or "leaf-shaped" points, are a distinct type restricted to the Still Bay techno-tradition of southern Africa. Henshilwood et al. (2001b: 429) state "We propose 'Still Bay sub-stage' as a regional, culture-stratigraphic term for assemblages with fully bifacially flaked, lanceolate shaped points." The bifacial points from BBC are made from silcrete, quartzite, and quartz. A macrofracture study of these points shows that some were used as spear points for hunting but that others probably served also as multifunctional tools (Lombard 2007). Approximately half of the silcrete points were heat treated and then finished using the pressure flaking technique (Mourre et al. 2010). Through three-dimensional form analysis, it appears that the shape of bifacial points gradually changed through time (Archer et al. 2015), which would indicate that the Still Bay was not a static technological entity. In addition, the methods used to manufacture the BBC bifacial points differ from those at another Still Bay site, Sibudu, 1000 km northwest of BBC (Soriano et al. 2015), which suggests that people creating bifacial points at these different

Blombos Cave: The Middle Stone Age Levels, Fig. 3 Location of Blombos Cave showing west section of the excavation. Upper M1 and M2 Lower, and M3 are occupation phases within the Middle Stone Age levels. The ages of each phase are shown at right (*OSL* optically stimulated luminescence, *TL* thermoluminescence, ka = 1000 years, U/Th = uranium/thorium)

locations were not necessarily part of the same, close, cultural entity.

Bone Tools (Fig. 4b): Bone tools are an unexpected technological innovation in the Still Bay at BBC. Regarded as a distinctive marker in the Eurasian transition to modern cognitive behavior, they are rare at MSA sites. More than thirty formal bone artifacts have been recovered from the Still Bay levels at BBC (Henshilwood et al. 2001a; d'Errico and Henshilwood 2007). The majority are awls made on long-bone shaft fragments, further manufactured by scraping and then used to pierce soft material such as leather, or small shells to make beads (d'Errico et al. 2005). At least some bone tools that were carefully polished after being shaped by scraping are probably projectile points made for hafting. It is noteworthy that points are treated differently to awls. The high polish on these points has no apparent function that can be detected but seems rather a technique that gives a distinctive appearance – an "added value" – to these artifacts. These may have formed part of a material culture exchange system among groups to maintain or even enhance social relations. The BBC bone tools provide comprehensive evidence for systematic bone tool manufacture and use, but we cannot be certain if this was also the case at other Still Bay sites. A note of caution is that we are not certain that the production of worked bone gives a modern character to all MSA material culture since little is known about the evolutionary significance of bone shaping (Henshilwood and Marean 2003). Symbolic marking on the bone is a likely feature that supports a symbolic interpretation. Microscopic analysis of a bone fragment marked with eight parallel lines from the Still Bay levels at BBC indicates they are the result of deliberate engraving and were possibly made with symbolic intent (d'Errico et al. 2001).

Engraved Ochres (Fig. 4c): Red ochre is a hydrated iron oxide with sufficient hematite (Fe_2O_3) content to be used as pigment. At BBC more than 2000 pieces of ochre, many bearing signs of utilization, have been recovered from

Blombos Cave: The Middle Stone Age Levels, Fig. 4 Artifacts from the Still Bay levels at Blombos Cave: (**a**) silcrete bifacial point, (**b**) formal bone tool, (**c**) engraved ochre SAM (AA-8938), (**d**) Nassarius kraussianus shell beads, and (**e**) ochre deposit on a shell bead (Images by C. Henshilwood & F. d'Errico)

the Still Bay phases. During excavations in 1999 and 2000, two ochre pieces with deliberately engraved cross-hatched patterns AA-8937 (Fig. 4c) and AA-8938 were discovered from the M1 phase (Henshilwood et al. 2002). Two ground facets are present on specimen AA-8937, and on the larger of these, the cross-hatched design is engraved. It is clear that the design results from deliberate intent and it is arguably among the most complex and clearly formed of objects claimed to be early abstract representations (d'Errico et al. 2003). Six additional engraved ochre pieces from the Still Bay phases have subsequently been recovered (Henshilwood et al. 2009).

Marine Shell Beads (Fig. 4d, e): A strong argument for early behavioral modernity in the Upper Paleolithic is the presence of personal ornaments. The discovery of more than 65 *Nassarius kraussianus* ("tick shell") beads in the Still Bay phases at BBC has added a new dimension to the modern human behavior debates (Henshilwood et al. 2004; d'Errico et al. 2005). All the recovered "tick" shells were carefully pierced using a bone tool to create a keyhole perforation. These were then strung, perhaps on cord or sinew and worn as a personal ornament. Repeated rubbing of the beads against one another and against the cord resulted in discrete use-wear facets on each bead that are not observed on these shells in their natural environment. These use-wear patterns are the principal factor that defines the shells as beads. Microscopic residues of ochre occur inside some of the beads and result from deliberate coloring or by transfer when worn.

The wearing and display of personal ornaments during the Still Bay phase was not idiosyncratic. Discrete groups of beads with wear patterns and coloring specific to that group were recovered from various levels and squares within the site (Vanhaeren et al. 2013). This patterning suggests that at least a number of individuals may have worn beads, perhaps on their person or attached to clothing or other artifacts. The shell beads also provide insights into

technological aspects of the Still Bay including the ability to drill, the use of cord or gut for threading, and the probable tying of knots to secure the beads. A comprehension of self-awareness or self-recognition is implied by the wearing of beads or other personal ornaments and was likely an important factor in cognitive evolution that was selected for long before the introduction of beads. Further, syntactical language would have been essential for the sharing and transmission of the symbolic meaning of personal ornaments within and between groups and also over generations, as is also suggested for the engraved ochre pieces.

Material Culture: Lower M2 Phase (c. 85 ka)

Bone tools, bifacial points, and shell beads are absent from the lower M2 phase. The intensity of the cultural deposits is low in this phase but includes a few basin hearths; a very large hearth in layer CGAC; small quantities of blades, flakes, and cores in silcrete, quartz, and quartzite; and some small ochre pieces. Some of the ochre pieces are ground or scraped but none have deliberate engravings. A detailed analysis of these artifacts is currently underway and the overall impression is that human occupations in the M2 phase were of short duration and possibly that the size of the groups was also limited.

Material Culture: M3 Phase (c. 100–94 ka)

In this lower phase, lithics are abundant and silcrete is the dominant raw material. Retouch on the lithics is rare, and the main characteristic of the industry is the predetermination of blank shape through core reduction (Douze et al. 2015). No bone tools have been recovered.

Modified ochre is common in this phase and eight slabs deliberately engraved with either cross-hatched, Y-shaped, or crenulated designs were recovered (Henshilwood et al. 2009). This indicates a tradition for the production of geometric engraved representation in the MSA at BBC with roots that go back in time to at least 100 ka and which includes the production of a number of different patterns. The findings support the view that the use of ochre during the MSA at BBC was not only functional but that it also served, perhaps primarily, in a symbolic role. In a wider context, this was also likely the case at other MSA sites in the southern Cape. Incised ochre pieces recovered from these latter sites also fall within the definition of engraved representations and demonstrate that there was a spatial and temporal continuity in the production and use of symbols in the region. The intrasite similarity of the abstract designs and methods used for the motifs at BBC and on regional intrasite level during the MSA is consistent with the continuity found in more recent symbolic systems that have been globally described for the Later Pleistocene and early Holocene.

Ochre-Processing Workshop, M3 phase (Fig. 5): In 2008 an ochre-processing workshop consisting of two toolkits was uncovered in the 100,000-year-old levels at Blombos Cave, South Africa. Analysis shows that a liquefied pigment-rich mixture was produced and stored in two *Haliotis midae* (abalone) shells and that ochre, bone, charcoal, grindstones, and hammerstones formed a composite part of the toolkits.

As both toolkits were left in situ and as there are few other archeological remains in the same layer, it seems the site was used primarily as a workshop and was abandoned shortly after the compounds were made. Dune sand then blew into the cave from the outside, encapsulated the toolkits, and by happenstance ensured their preservation before the next occupants arrived, possibly several decades or centuries later.

Recent support for a southern African origin for *H. sapiens* comes from genomic and phenomic diversity studies. The recovery of these toolkits at Blombos Cave adds evidence for early technological and behavioral developments associated with *H. sapiens* to this scenario. It documents the first known instance for the deliberate planning, production, and curation of a pigmented compound and for the use of a container. Evidence for the complexity of the task includes procuring and combining raw materials from various sources (implying they had a mental template of the process they would follow), possibly using pyrotechnology to facilitate fat extraction from bone, using a probable recipe to produce the

Blombos Cave: The Middle Stone Age Levels, Fig. 5 Ochre-processing toolkits in situ showing toolkit 1 (Tk1) (**a**) and toolkit 2 (Tk2) (**b**) (Images Grethe Moéll Pedersen)

compound, and the use of shell containers for mixing and storage for later use. An elementary knowledge of chemistry and the ability for long-term planning suggest conceptual and cognitive abilities previously unknown for this time and serve as a benchmark during the early evolution of the technological and cognitive abilities of *H. sapiens* in southern Africa (Henshilwood et al. 2011).

Subsistence in the MSA Levels

The faunal collection from Blombos shows that MSA people practiced a subsistence strategy that included a very broad range of animals. This means they were able to hunt large animals, such as eland, but also gathered, collected, or trapped small animals such as tortoises, hyraxes, and dune mole rats. They also brought seal, dolphin, and probably whale meat back to the cave. The latter two were almost certainly scavenged from beach washups, but seals may have been speared or clubbed.

The shellfish provide early evidence for the use of seafoods. Shellfish were collected and brought back to the cave, and the M3 phase, with an age of c. 100 ka, is a particularly rich shell midden. Common species include the giant periwinkle (*Turbo sarmaticus*), limpets (Patella sp.), and brown mussels (*Perna perna*). Species variations may, with larger sample sizes, inform us of past changes in ocean paleotemperatures.

Fish remains are present, but not abundant, in all phases at BBC. Fish remains are more abundant in the LSA, but a wider range of species are present in the MSA. Chemical analysis of fish bone from the LSA and MSA levels using the carbon/nitrogen method confirms the antiquity of the MSA specimens. Most of the species present are not known to wash up after cold-water upwelling events; hence, scavenging of washups was not the primary source of fish. No artifacts that appear to be obvious fishing equipment have been found, but the range and sizes of species present indicate that a number of methods must have been employed. These include baited hooks, spearing, and tidal traps. Comparison of the elements from the same species that have survived in the MSA relative to the LSA at BBC has shown a large deficit in the MSA – in other words, age-related taphonomic processes have resulted in the loss of many fish bones, and there were likely many more fish deposited in the MSA than we can currently see. Fish are seldom reported from other southern African MSA sites, and by implication, it was thought that MSA people

were incapable of exploiting coastal resources efficiently. The evidence for fishing at BBC and Klasies River contradicts this theory (Van Niekerk 2011).

The overall subsistence pattern at BBC signifies that no clear distinction can be made between Later Stone Age and Middle Stone Age subsistence behavior at the site (Henshilwood et al. 2001b; Henshilwood 2008). The implication is that during the MSA occupations, the subsistence mode was essentially modern.

Human Remains

The amount of human material recovered from the Blombos MSA is small – seven teeth (Grine et al. 2000; Grine and Henshilwood 2002). The crown diameters of at least some of these teeth suggest that the people at Blombos were probably anatomically modern. This conclusion is supported by similar evidence from a nearby archeological site, Klasies River, that dates to a similar time period.

Summary

The origins of "modern" human behavior generate lively debate, worldwide, but an African evidence for its origins has long remained elusive. Published results from the Blombos Cave excavations complement recent and older findings from a number of African MSA sites that suggest some aspects of "modern behavior" evolved during the early Late Pleistocene in Africa. The discoveries at Blombos clearly reflects the acquisition of fully modern cognitive abilities by southern African populations by at least 100,000 years.

Blue Shield

Corine Wegener
U.S. Committee of the Blue Shield, Minneapolis, MN, USA

Introduction

The last quarter century has been a particularly traumatic period for cultural heritage exposed to damage by armed conflicts and natural disasters. Armed conflicts can be international or internal in nature, often causing humanitarian casualties as well as damage to cultural heritage. The damage is often deliberate, as in looting of sites and collections or the destruction of cultural heritage as a part of ethnic strife. Bosnia, Kosovo, Afghanistan, Iraq, Georgia, Egypt – these are just a few of the countries which have seen damage done to their heritage in recent years. Natural disasters were even more numerous in this period and were often more deadly and destructive than armed conflicts.

Since 2005, the International Council of Museums Disaster Relief Task Force (ICOM DRTF) has monitored at least 27 natural disasters affecting cultural property (taken from unpublished email correspondence between ICOM-DRTF members.) These include the Indian Ocean tsunami, the Haiti earthquake, and the Japan earthquake/tsunami/Fukushima nuclear meltdown, among many others. Natural disasters and armed conflicts are obviously here to stay and, in fact, may increase with global climate change and political instability. The Blue Shield may offer some hope to prevent or mitigate damage to cultural property in future disasters through networking, monitoring, and emergency planning and response.

Definition

The Blue Shield is an overarching term describing a group of organizations whose goal is to promote the protection of cultural property in the event of armed conflict and natural disasters. These are divided into the International Committee of the Blue Shield (ICBS) and its member organizations, the Blue Shield National Committees (BSNCs) and their individual and organizational members, and the Association of National Committees of the Blue Shield (ANCBS). The Blue Shield organizational structure is loosely based on the Red Cross model, which includes the International Committee of the Red Cross (ICRC), the various Red Cross committees in each individual country (such as the American Red Cross), and the International Federation of the Red Cross (IFRC), which helps coordinate the activities of the national committees. The Blue Shield is sometimes referred to as "the Red Cross for culture."

Historical Background

A follow-up to the 1899 and 1907 Hague Conventions (both setting forth rules of war), the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict is the first international treaty dealing exclusively with cultural heritage during war. Drafted in response to the damage and looting of cultural heritage during World War II, the 1954 Hague Convention deals primarily with conflicts between nations and describes each nation's responsibilities toward cultural heritage (1954 Hague Convention, Chapter 1). Basically, these include planning during peacetime for the protection of each nation's domestic cultural property should an armed conflict occur and to safeguard and respect the cultural property of other States Parties with whom they are in armed conflict. The treaty also describes the protective symbol of the Blue Shield and the terms of its use to designate protected cultural property and personnel (Fig. 1).

The 1954 Hague Convention was violated repeatedly during the Bosnian conflict (1992–1996), with evidence that some military forces deliberately destroyed cultural sites bearing the blue shield, the international symbol for the protection of cultural property during armed conflict. This included the destruction of multiple mosques, minarets, churches, and other religious institutions, along with the infamous shelling of the historic city of Dubrovnik and the Stari Most

Blue Shield, Fig. 1 Blue Shield symbol used to mark the archaeological site at Tikal in Guatemala. (Photo courtesy David Mitchell)

Bridge. Several individuals have been charged with war crimes under the United National International Criminal Tribunal for the former Yugoslavia.

The situation in Bosnia initiated a discussion within the international cultural property community about how to better support the 1954 Hague Convention. The International Committee of the Blue Shield was founded in 1996 and is headquartered in Paris, also the home of UNESCO, which administers the Hague Convention treaty. In addition, a Second Protocol to the Hague Convention was drafted in April 1999 and came into force in 2004. Its purpose is to strengthen the main convention by including more specific language about punishing violations.

Key Issues/Current Debates

International Committee of the Blue Shield (ICBS)

ICBS consists of the International Council on Archives, the International Council of Museums (ICOM), the International Council on Monuments and Sites (ICOMOS), the International Federation of Library Associations (IFLA), and the Coordinating Council of Audiovisual Archives Associations (CCAAA). Its board is made up of the five directors general of these organizations with a rotating presidency. While ICBS does not have a permanent office or staff, the staffs of these individual organizations coordinate and carry out the daily activities of the ICBS.

The mission of ICBS is to "work for the protection of the world cultural heritage by coordinating preparations to meet and respond to emergency situations as well as post-crisis support" (http://icom.museum/what-we-do/programmes/museums-emergency-programme/international-committee-of-the-blue-shield.html). The Second Protocol to the 1954 Hague Convention mentions ICBS and recognizes its role as an advisory body to international organizations such to the intergovernmental Committee for the Protection of Cultural Property in the Event of Armed Conflict at UNESCO and the International Criminal Court.

National Committees of the Blue Shield

Blue Shield national committees (BSNCs) strive to mirror the structure of the ICBS as closely as possible by including the national equivalent cultural organizations. For example, the International Council of Museums–USA is a founding member of the US Committee of the Blue Shield and represents the interests of museum professionals interested in implementing the 1954 Hague Convention here in the USA.

Each BSNC must apply for and receive official recognition from the ICBS; however, there is a great deal of flexibility from country to country. In some countries, the BSNC is a function of the Ministry of Culture or some other government body; in others it may be formed by other NGOs or organizational members, and in still others, such as the US, it may be a nonprofit organization with both individual and institutional members.

There are now more than 20 BSNCs, with many more under construction. Their primary mission is to promote implementation of the 1954 Hague Convention in their individual countries. The treaty is essentially a legal agreement between nations, and the BSNC members, as citizens of their respective nations, can influence political leaders, coordinate and train their militaries, and generally raise public awareness. In addition, BSNCs have a responsibility to raise awareness about the importance of domestic emergency preparedness and response for culture, both within their own countries as well as to help colleagues abroad. This may take place either as part of their own national humanitarian response or as part of the Blue Shield network. (see www.uscbs.org for an example of a BSNC).

An emerging function of BSNCs may be an active role in raising military awareness about protecting sites during armed conflict. Prior to the 2011 NATO "No-Fly Zone" in Libya, the US Committee of the Blue Shield worked with archaeologists and other NGOs within the Blue Shield network such as ICOM, ICOMOS, and the Archaeological Institute of America, to produce a list of coordinates of important Libyan cultural sites. USCBS then shared this information with the US Department of Defense prior to the

initiation of the no-fly zone, resulting in minimal damage to cultural sites during the NATO bombing.

Association of National Committees of the Blue Shield (ANCBS)

ANCBS was formed by a group of BSNCs and the ICBS by the 2008 Hague Accord to better coordinate the efforts of BSNCs, particularly with regard to emergency response (www.ancbs.org). The founding of ANCBS came in part from the feeling among cultural heritage professionals that there was not a timely or effective international response to the looting of the Iraq National Museum in 2003 and that BSNCs could better coordinate an emergency response in such situations. It also seemed natural that the National Committees have their own organizational structure for mutual coordination.

The ANCBS board consists of members (mostly the presidents or chairs) of various BSNCs and is based in The Hague, which in addition to being the home of the 1954 Hague Convention is also deemed the "international city of peace and justice" because it is home to the International Criminal Court. The board meets regularly in The Hague and in other cities around the world, as well as with the ICBS board in Paris.

Current Debates

One roadblock to the success of the Blue Shield is the perception that it is wrong to worry about saving culture during natural disasters and armed conflicts. While humanitarian assistance must always come first, a response for cultural property often comes too late or does not come at all. Up until recently, it has also been left out of emergency planning and response. This is changing slowly and is an area where BSNCs can make a real difference by raising awareness in their respective countries. One recent example is the US Committee of the Blue Shield's organizing a partnership with a number of US NGOs and government organizations after the 2010 Haitian earthquake. As a result, a very small percentage of the total US government humanitarian aid package for Haiti was set aside for culture, resulting in the Smithsonian Haiti Cultural Recovery project (www.haiti.si.edu).

Future Directions

As more BSNCs develop and ICBS becomes better staffed and funded, Blue Shield will become a more effective advocate for implementation of the 1954 Hague Convention and for emergency response for cultural heritage. Better preparedness and increased awareness among the population, governments, and military leaders will hopefully lead to a decrease in the loss to our shared cultural heritage worldwide.

Bobrinsky, Alexander A.

Yuri B. Tsetlin and Helena V. Volkova
Institute of Archaeology at Russian Academy of Sciences, Moscow, Russia

Basic Biographical Information

Alexander Afanasievich Bobrinsky (1930–2010) (Fig. 1) was an outstanding Soviet and Russian researcher of ceramics and ancient pottery production. From 1952 until 1956, Bobrinsky was a student of the History Department at the Lenin Moscow State Pedagogical Institute, and during 1959–1962, he was a postgraduate in archaeology in Lomonosov Moscow State University under the scientific leadership of corresponding member of Russian Academy of Sciences, Artemiy V. Artsihovsky. In 1962, Bobrinsky successfully finished a thesis titled *Pottery Wheels of Eastern Europe in 9–13th Centuries AD*, and in 1979, he completed his doctor of history thesis, *Pottery Production in Eastern Europe. Sources and Methods of Study.* From 1963 until 2010, he worked as a leader of the History and Ceramics Laboratory at the Institute of Archaeology Russian Academy of Sciences.

As early as 1959, Bobrinsky began to collect a database of ethnographic information on the rural pottery production of various peoples from Eastern Europe, the Caucasus, and Central Asia. That work included, on the one hand, mass and systematic fill-in-the-blank requests of the population of these regions, and, on the other hand, many years of studying at recent rural pottery production centers. This work produced a tremendous resource of ethnographic data from about 1,000 pottery centers of European Russia, Baltic countries, the Ukraine, Belarus, Moldova, Caucasus, and Central Asia. This compendium became the basis for deeper understanding of important regularities in the history of ancient pottery production.

Bobrinsky, Alexander A., Fig. 1 Alexander Afanasievich Bobrinsky

Major Accomplishments

A.A. Bobrinsky is a creator of the new "Historical-and-Cultural Approach" for analysis of ancient pottery production. The core of this approach consists of the reconstruction of concrete potters' skills and cultural traditions in pottery technology, vessels' shapes, and pottery decoration through archaeological ceramics. In this field, A.A. Bobrinsky elaborated a general system of pottery technology investigation (1978, 1999), and new methods to study the shape of vessels (1987, 1988, 1991). Furthermore, his research revealed the main historical regularities in the development of special constructions for firing of vessels – bonfires, ovens, stoves, and kilns (1991, 1993). Moreover, Bobrinsky proposed well-proven new theories of the emergence, initial development and evolution of pottery wheels (1993, 1996), pottery kilns (1991), and ancient pottery production as well (1993, 1997, 1999, 2006). In recent years, he has focused a lot of attention on methods for studying the sex and age of ancient potters, ascertained through the nail prints on ceramics (2008).

All the new methods elaborated by Bobrinsky aimed to solve a core scientific goal – ceramics as a valuable source of historical information on ancient populations. A.A. Bobrinsky always tried to impart his knowledge to young scholars and that is why a strong scientific school in the study of ancient ceramics and pottery production now exists in Russia and in the countries of the former USSR.

Bolt-Holes of Kilimanjaro, Northern Tanzania

Valence Valerian Silayo
Department of History, Stella Maris Mtwara University, Mtwara, Tansania

Introduction

Internal and external conflicts and frictions within the society has been part of the society's complexity. Such conflicts usually result onto direct confrontation between one group within the community and against another neighboring community. This has led human society to develop various war techniques and tactics to both defeat the enemy and shield its subjects. The origin, development, and complexity of such war defense mechanisms differed from community to community, location, and natural environment. Therefore, defense strategies developed by such societies form one of the most important processes in human history, as it has fundamentally changed social stratification and defined the complexity of the society and its cultural development. This has as well created professionalization and social inequality – standing army, army generals, and other leaders – ownership and distribution of natural resources. Because of these significances, the study of the ancient society's defense structures such as underground tunnels, trenches, ditches, and stone fortification has been one of the most important topics in the field of archaeology, anthropology, history, as well as other related disciplines of sciences and social sciences. This entry provides an account of a precolonial underground tunnel in Northeastern Tanzania.

Definition

The Chagga precolonial bolt-holes can be defined as a subterranean where a person can escape and hide. These are underground security chambers artificially constructed and are purely a local innovation. Bolt-holes were used as fastness for people and their goods during wars. The Chagga are a Pasto-agricultural community settling on the southern slopes of Mount Kilimanjaro. They are well-known for their economic and political enterprise and have a long history and reputation as ambitious, entrepreneurial, and adaptable (Fisher 2012; Pietilä 2007). According to Mkenda (2009, p. 60) *Wachagga* in (plural) and *Mchagga* (singular) have or shared "sufficiently, though inexhaustively" common cultural traits along with their language known as KiChagga. Scholars of Chagga literature maintain the form "Chagga" as both noun (singular and plural) and adjective.

This usage has been followed whenever possible throughout this thesis. The Chagga have acquired different interpretations from different scholars. Some refer to them as "mountain people," (Mkenda 2009, p. 60) as they identify strongly with Mount Kilimanjaro. Some used it as a place name (Krapf 1960[1860]); Meyer 1891) and some used the term to refer to people (Krapf 1960 [1860]). It is stressed here that from the early travelers' documents, the Kilimanjaro people have been bearing this name probably from the beginning of the second millennium CE or earlier; this is contrary to the suggestion by Stahl (1964) and Wimmelbücker (2002) who argue that "Chagga" was a place name with no reference to people and that the population on Kilimanjaro started to bear the name only from the 1890s.

Historical Background

The term "Chagga" is complex and sometimes perplexing. Plausibly, the first uses of the term "Chagga" and most especially its appearance in written records connoted that it was a unifying word signifying a common identity to the Chagga people of Kilimanjaro (Bender 2013). From the time of European exploration of colonies by missionaries, explorers, and traders and all the events at the beginning of the 1890s, the mountain's disparate residents had been referred to as a single people – the Chagga. "This designation argues Bender, probably stemmed from their perception of the mountain as a single, unified landscape, as well as from the similarities of the various mountain communities in terms of agricultural and cultural practices" (Bender 2013, p. 200). In written documents, the term appears as Mchagga, Wachagga, Chagga, Chaga, Waschagga, Jagga, WA-caga, or Dschagga, all referring to the same people. This thesis uses the term "Chagga" because it is the common usage and the most preferred by the Chagga people whom I interviewed.

Almost all scholars who have written about the Chagga from the eighteenth century to date used the term differently (Bender 2013; Campbell et al. 2004; Moore 1986; Moore and Puritt 1977; Stahl 1964; Yakan 1999). Some scholars have referred to the Chagga as a subculture of the Bantu inhabiting the fertile yet crowded slopes of Mount Kilimanjaro (Yakan 1999). This group is among the most politically active, entrepreneurial, and best educated in Tanzania (Stahl 1964). Chagga entrepreneurial culture is unique and acknowledged throughout the country. This culture can be traced from precolonial times, especially from the 1600s when the Chagga were actively engaging in regional trade. They traded with the Kamba to the north linking to the Mazrui Empire in Mombasa. When the Mazrui Empire declined and Zanzibar further to the south rose, the trade caravan through Ukamba also collapsed (Stahl 1964). The caravan now opted to move between the coast and Lake Victoria. This route took them across the southern slopes of Kilimanjaro. The Chagga benefited again in this trade making them the main group who supplied provisions to the caravan in addition to a safe passage. This led to the development of the Chagga states and increased social complexity through power, wealth, and vibrant agricultural economy (Campbell et al. 2004, pp. 46–50; Moore and Puritt 1977, pp. 11–15; Stahl 1964).

Generally, the whole question of Chagga origin, settlement, and identity needs to be given further thought. More fresh data, mostly archaeological data, is required. Works by Soper in Northeastern Tanzania and southeast Kenya shed only some light for Kwale and Maore pottery ware and related types which date to around the first millennium CE. These dates relate to Bantu-speaking groups, of which the Chagga are one. However, Soper (1982a, p. 235, b) makes very clear that evidence for the later Iron Age, particularly for explaining the spread of the Bantu, is scattered, fragmentary, and undated. Hence, there is a need for fresh well-documented chronological data for dating, to establish a clear historical origin, identity, and settlement pattern in Kilimanjaro.

Natural caves and other underground man-made features have played very important role in shaping the history of mankind. Such structures reflected and defined the relationship between man and his environment (Mostafa 2012, p. 37). Human being has been using the underground environment for war purposes since about 5500

BP (Eastler 2005, p. 21). Eastler is of the opinion that the use of natural cave might date back much earlier in human history. Ancient Egyptians provide us with the best example of development and use of the underground "especially in the construction of: tombs, warehouses, water passages, and tunnels which were used as accesses to tombs, worshipping rooms and the warehouses" (Salam 2002, p. 295; Mostafa 2012). This entry focuses on the Chagga and the precolonial tunnels (Figs. 2 and 3) in Kilimanjaro – Tanzania (Fig. 1). The bolt-hole were widely used system of defensive

B

Bolt-Holes of Kilimanjaro, Northern Tanzania, Fig. 3 A section of Malanje bolt-hole in Kibosho – the arrow point to a recess chamber

structure in Kilimanjaro. Every Chagga village constructed and used these underground mega features. There are no established chronologies of the bolt-holes; however, oral accounts in Kibosho trace this technology from Mangi Tatuo who ruled Kibosho between 1861 and 1862 (Silayo 2009; Stahl 1964). The underground structure (Fig. 3), known as *"ndeshe" singular/ "mireshe" plural*, was very complex. The enemy could not easily follow when the Chagga retreated. They have features like alcove chambers – occupied only by soldiers when retreating. Several of such recesses were observed during detailed survey of the Mamsera, Mwika, Marangu, and Kibosho bolt-holes. These structures were found to have several cubicles for various functions such as kitchen, store, sleeping, and livestock chambers.

The choice of location for construction of the bolt-hole was very important. According to oral histories, river banks and forested areas with heavy vegetation were preferred. Clack (2009) examined the Laban cave (surveyed and documented by Silayo 2012) and Nkowoyo Kyalia bolt-hole and argues that the two bolt-holes were strategically placed. The area has also been characterized with heavy forest which impeded visibility as well as sound (Fernandes and Nair 1986). The significance of the monumental archaeological remains and other material culture found in Kilimanjaro lies in the fact that they have ideological and affective connotations attached to them. For example, the Chagga underground bolt-holes and royal compounds speak volumes about the complexity of the Chagga precolonial society. These are intrinsically connected to the Chagga precolonial polity with which the Chagga as a group are proudly identified; as Festo Mkenda (2009) puts it, the Chagga identify themselves with a group rather than as individuals.

Climate of Kilimanjaro

Muller (1983) presents Kilimanjaro area as defined by a "seasonally dry, tropical climate." The area also has four hydrological seasons with bimodal rainfall pattern (Schüler and Hemp 2016). Schüler and Hemp further argue that climate in Kilimanjaro depends on the elevation on the mountain as well as the exposure of the mountainside (Schüler and Hemp 2016, p. 2) This could have been the reason for Juhani Koponen's argument that Chagga were not in position to suffer

food shortage (Koponen 1988, p. 645), and if it had happened, then it would have been in the areas torn by war.

Scholars have argued that the Chagga knowledge of the seasons and climate is affected much by their immediate environment such as the coffee-banana belt, the forest, and cultivated lands (Blot 2006). For the Chagga, water supply represents "large-scale climatic patterns" and determines climatic development (Tagseth 2010). Variation in water supply means change of climate and seasons which also influences cultural and social life. To keep pace with the climate and seasonality, the Chagga had to pay attention to the direction and movements of clouds. Oral histories contend that with the traditional knowledge on climate and seasons, they could tell when there would be heavy rain and the direction of the rain. For example, if the heavy rain cloud was observed on the plains and possibly moving toward the mountain, then they would receive heavy rain in the farmland and banana-coffee grove. If the cloud was spotted stationary on the mountain, then rivers would flood as it was expected to rain in the forest. This knowledge triggered the Chagga to prepare their farms and furrows in a timely manner. Blot (2006) argues that there is a key dissimilarity between the traditional view of climate and that of the modern climatologist. He says that the difference is that the traditional view of climate pays attention only to describing the cloudy season, while modern climatologists also attend to hydrological cycles, plant growth, and harvesting. The Chagga cultural life cycle had to match climate as they relied on the good rainfall both to water the farms and to fill the furrows, which were their main engines for survival. Therefore, climatically, reliable rainfalls on the slopes, with differentiations according to altitude, facilitated agriculture that supported relatively dense populations. Principally the Chagga people quite heavily populate the area surrounding the mountain. Presently, the Chagga people still use the forest for many household and medicinal products, for fuel wood, small-scale farming, beekeeping, hunting, charcoal production, and logging. Such activities indicate close attachment and social interaction with the mountain on one side and the Chagga population on the other side (UNEP-WCMC 2011).

I argue that it is by understanding the Chagga's view of environment and their culture – the relations between humans (Chagga) which act as a social link and their environment, which act as a natural link –that we can understand the nature of the Chagga social complexity. Analysis of the relationship between the mountain and the Chagga shows that they attach strong symbolic meaning to their environment. This profound attachment, argues Sébastien (2010, p. 2), leads to social relations and technical progress while conflicts over natural resources are primarily of a social nature.

Therefore, the fertile, well-watered slopes of Mount Kilimanjaro have for millennia been home to Chagga society. Ancestors of the present populations began to settle the lower slopes of the mountain in successive waves from 500 CE. Settlements tended to be located on river banks/ridges, rivers, and streams with fast-moving water heading toward the plains. These rivers acted as boundaries. The Chagga, exploiting numerous rivers for irrigation, developed an agrarian economy based upon intensive cultivation. Over several centuries, this led to each ridge of the mountain developing into an autonomous political space comprised of several different clans, each led by a leader called Mangi and ceremonial specialists (Bender 2013; Moore and Puritt 1977). Though politically independent, clans on the same ridge often forged alliances for purposes such as defense and also had regular contact through both warfare and trade (Bender 2013; Wimmelbücker 2002). Under these conditions in mind, Chagga could have developed a form of complex social political units building strong defense structures such as bolt-holes and other earthworks.

Key Issues/Current Debates

There are some issues of concern about Chagga bolt-hole – origin of the idea, technology, personnel, and tools used for construction as well as name of the structure – these issues warrant a

further research and inquiry into the Chagga oral history. I have argued that the Chagga did not borrow bolt-hole technology from any neighboring country and one cannot say certainly that it was brought by migrants. This is due to the fact that, apart from Gweno people, there are no records of similar structures in the neighboring countries. Although the Gweno people from the pare Mountains, south of Kilimanjaro, have the same kind of defense, scholars agree that the technology was borrowed from the Chagga and sometimes the Chagga were hired by chiefs from Pare and Usambara hills to construct the bolt-holes in exchange for hoes and other iron implements such as spears and swords, as well as animals like cows and goats (Fosbrooke and Sassoon 1965). Although the issue of tools and construction method has not yet been cleared, this is a local origin and innovation. The Chagga made proper use of local resources and topography of their land to device security measures to keep them safe. The different names used by various scholars to refer to the bolt-holes are of more of stylistic than semantic. Scholars would choose name for depending on what they think the structures are and look like. For example, scholars have used different names to refer to these structures: they include Chagga underground bolt-holes (Clack 2009; Fosbrooke 1954; Fosbrooke and Sassoon 1965; Silayo 2009, 2012), dugouts (Jones 1941), hideouts (Tagseth 2008), and caves (Chami 2005).

International Perspectives

These were used purposely to protect the chiefdom's power and wealth. Andrew Reid describes a ditching system in Uganda and argues that the ditches date to the fifteenth century and were dug on the hilltop. The ditches were cut to a depth of about five meters and run for more than a kilometer (Reid 2013). He further argued that the lack of tangible evidence for the settlement of the sites with ditches disqualifies the argument that they were used for defensive purposes; rather, he argued that ditches represented power and were associated with rituals, spirits, and the seat of the political authority (Reid 2013).

Generally, earthworks have been used to explore chronology of settlement and development of social complexity in precolonial societies and suggest a complex social and political organization (Boachie-Ansah 2013, p. 37). This is due to the fact that, argues Kiyaga-Mulindwa (1978, p. 196), earthworks are a result of intensive labor bringing in a considerable proportion of the population. The amount of work and labor force and complexity of the structures strongly suggest well-organized social organizations that express a high level of mobilization, control, and coordination (Boachie-Ansah 2008.) The Chagga tunnels and earthworks are no exception. They express the sophistication and complexity of the community during the precolonial epoch and, as Clack (2009, p. 325) put it, played a very significant role in the Chagga "cultural relations."

Future Directions

Though many works have been done in the last decades, there are still issues under debate. Issues like construction methods and tools, dating of the structures, allocation of functions for the room by gender and hierarchy, and the whole theoretical discourse of social complexity and emergence of chiefdoms, such as the role played by the defense structures in the process of social complexity among the Chagga and what role did it play in defining the nature of the Chagga chiefdoms. This calls for more sophisticated multidisciplinary digital methods such as GIS in archaeology, aerial and satellite images and photographs, ground-penetrating radar for locating artifacts hidden below ground, as well as LIDAR which can scan the surface through vegetation. An interdisciplinary approach to study chiefdoms and social complexity in Africa has also been used successfully in southern Africa by Eldredge (2015). She uses detailed and wide knowledge of oral and archival sources coupled with archaeological and linguistic sources to compare independent forms of evidence that point to similar developments and articulate the relationship between the growth of chiefdoms and the emergence of social complexity in Southern Africa. The use of these methods

in Tanzania, therefore, will help to further understand the ditches and underground bolt-holes of the Chagga as well as locating more artifacts that could be used to shed more light on the Chagga history. The wealth of precolonial cultural heritage observed in Kilimanjaro is just a fraction of what may be discovered among the 120 ethnic groups found in Tanzania. The most dominant and powerful kingdoms such as the Hehe, Pare, and the Nyamwezi are well studied ethnographically, but their historical archaeology remains *terra incognito*. Archaeologists have to widen researches to cover aspects of chiefdoms, identity, and social complexity. This will enhance a holistic understanding of the precolonial history of Tanzania, Eastern Africa, and Africa in general.

Basic Biographical Information

Duccio Bonavia, born in Spalato (Dalmatia) on March 27, 1935, was the son of Aurelio and Neda Bonavia, both native Italians. After the Second World War, when Duccio was 14 years old, his family moved to Peru in July 1949 and settled in Lima. In 1965, Duccio received his Peruvian citizenship while still retaining his Italian citizenship (Fig. 1).

Bonavia, Duccio, Fig. 1 Duccio Bonavia

Duccio received his primary education from a school in Spalato (1940–1944) and his secondary education in Bassano del Grappa, Possagno, and Treviso (1945–1947). He finished his high school studies at Colegio Italiano Antonio Raimondi in Lima (1950–1951). He then enrolled in the National Engineering School, today known as the National University of Engineering, where he intended to study architecture (1952–1954). Duccio, however, did not enjoy his engineering courses and soon switched to the University of San Marcos (1955–1960) where he studied archaeology and anthropology.
